6.2 Kitikmeot Region

6.2.1 Community Results Discussion: Bathurst Inlet

The survey frame:
An assessment of under-enumeration indicated that there were very few hunters who were not registered in the Harvest Study.

Given the small size of this community there were only three hunters registered in the active and intensive classifications in most years. All classifications were joined and harvest estimates were calculated for all hunters together; there was no stratification used.

Survey coverage and non-response bias:
There was a lot of month to month variation in response rates during the study. In general years 2, 4 and 5 were more problematic having rates below 75% in two to four months of the year. As the study progressed many of the hunters moved to other communities, such as Cambridge Bay or Kugluktuk, for the winter months. Unlike the practice in most other communities when this occurred (see Section 3.2), hunters were not always added to registration lists in their new community but continued to be interviewed as Bathurst Inlet hunters since they would return there every summer. Many of the months with low responses were during the winter when hunters were living in other communities either for work or for school and were not reached for interview. As seen in Table 9 the consistent intentional non-response rate in Bathurst Inlet was nil and therefore was not a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough in most months in all years to ensure that n did in fact constitute a sufficiently representative sample of N hunters. However, with the exception of year 3 there were months with low response rates during each year of the study. Readers should exercise caution when using the data collected during these months since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:
During the time of the community visits held in the Kitikmeot region in the winter of 2003 most hunters from Bathurst Inlet were living in other communities and the HTO was not active. It was not possible to hold consultations on the data. However, the Fieldworker did report that most hunters in the community used their calendar during the study and reported their harvests accurately.

6.2.2 Community Results Discussion: Cambridge Bay

The survey frame:

An assessment of under-enumeration during the community visit revealed that there were approximately 55 hunters who were not registered in the Harvest Study. Thirty-seven of these were Inuit – all occasional hunters. It is estimated that there were 18 non-Inuit hunters with assigned hunting rights who were not registered – 16 occasional and two active hunters. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. However, the extent of the bias is likely small since although the missing hunters represent 12 percent of the total hunter population, they are mostly occasional hunters (Table 10). Harvests for the unregistered hunters can be estimated using mean harvest quantities for each species by strata. However, these estimates, having their own sources of error and bias, are beyond the scope of this Final Report. Readers may apply to NWMB to obtain the results of these calculations.

Due to the relatively small number of intensive hunters registered in Cambridge Bay, the intensive classification was joined with the active classification for the purpose of calculating harvest estimates.

Survey coverage and non-response bias:

Response rates in year 1 of the study were low with all months below 75%. However, response rates in years 2 to 5 were very good. As seen in Table 9 the consistent intentional non-response rate in Cambridge Bay was low, at 0.4%, and was not thought to be a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough during years 2 to 5 to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during year 1 of the study since the potential for both sampling error and for non-response bias increases as response rates fall.

Measurement issues and response error:

It was reported during the community consultations that egg harvests were under-reported. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, recall periods were long during the first year of the study, particularly during the first six months when the majority of the harvest records were collected over six months after the harvest. However, recall periods improved in subsequent years when the vast majority of the harvest records were collected within three months of the harvest. The longer recall periods in year 1 may have introduced some measurement error due to a reduced ability of hunters to remember their harvests.

Throughout the study there were commercial harvests of musk-ox, arctic char and some caribou. Most of these harvests were never reported during the Harvest Study or were removed from the database before calculating harvest estimates (see Table 4). Harvest estimates should be viewed as an indication of the subsistence harvest only.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of both barren-ground caribou and island caribou. Also, some hunters did not specify the type of caribou harvested. For the purpose of calculating harvest estimates they were combined into one category.
2. **Musk-ox:** As well as a subsistence harvest, there is also commercial harvesting of musk-ox and musk-ox sport hunts in Cambridge Bay. The Harvest Study set out to collect subsistence harvest data only. The harvest estimate in year 1 however, may contain some commercial or sport hunt data (C.F.). DSD reports the following subsistence harvest numbers for musk-ox (DSD MXb):

Year 1	Year 2	Year 3	Year 4	Year 5
n/d	20	15	17	14

   These numbers are thought to be accurate and indicate that study harvest estimates are a little low in some years but are in the right range.
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).

[4] **Wolf:** Harvest estimates seem too low (C.F.). Data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for years 4 and 5 and indicate that 28 wolf pelts were purchased in 1999/2000 (year 4) and 9 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Based on this information the harvest estimate for year 4 does appear low however the estimate in year 5 may be high.

[5] **Arctic fox:** Hunters sell most of their harvest, so to verify the harvest estimates data were obtained from DSD detailing the number of pelts sold by hunters (C.F.). Again, DSD provided reports for 1999/2000 and 2000/2001 (years 4 and 5) which indicated that 260 arctic fox pelts were purchased in year 4 and 489 were purchased in year 5 (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). This information confirms that Harvest Study estimates seem to be in the right range.

[6] **Wolverine:** Harvest estimates may be somewhat low but comments were also received during the community visit which indicated that estimates seemed reasonable (C.F.). A total of 6 carcasses were submitted from 2000 to 2001 to DSD for their ongoing monitoring program. However, not all carcasses are submitted for this program (DSD WV).

[7] **Seals:** Seal harvesting consists of mainly ringed seals but some bearded seals are also harvested. The harvest estimate for ringed seals in year 5 seems high (C.F.).

[8] **Geese:** Harvest estimates for snow geese are thought to be low and it was suggested that many of the unidentified geese may be snow geese. However, Ross' geese and brant geese are also harvested in the area but none were reported. The Canadian Wildlife Service had a program in place in year 5 to encourage snow goose harvesting, so it is suspected that most of the unidentified geese in year 5 were actually snow geese (C.F.).

[9] **Eider duck:** The community harvests both king and common eider ducks each year (C.F.).

[10] **Ptarmigan:** The harvest estimate in year 2 seems too low. Estimates in other years look more accurate (C.F.).

[11] **Eggs:** There are many eggs harvested each year. Eggs were not reported by hunters; one hunter commented that the Fieldworker never asked about eggs and many hunters did not think to report them. A person can easily collect over 200 eggs in a day. All egg estimates seem too low (C.F.).

[12] **Arctic char:** Commercial fishing of arctic char took place in about five lakes during the Harvest Study (DFO F). Some of these data were reported by hunters but were removed from the subsistence harvest in the database and can be viewed in Table 4. If the hunter did not specify that the harvest was commercial these data would be retained in the database and included in the harvest estimates. In general though it is thought that the harvest estimates represent the subsistence harvest of the community (C.F.).

[13] **Whitefish:** The harvest estimate in year 5 seems too low, as does the mean annual harvest (C.F.).

[14] **Ocean fish:** The species of fish was not identified but hunters report that they were likely cod (C.F.).

[15] **Cod:** Harvest estimates seem low. Estimates should be closer to the 1000 fish range (C.F.).

6.2.3 Community Results Discussion: Gjoa Haven

The survey frame:

An assessment of under-enumeration during the community visit revealed that there were approximately 22 hunters who were not registered in the Harvest Study. Eighteen of these were Inuit – all were occasional hunters. It is estimated that there were four non-Inuit hunters with assigned hunting rights who were not registered, also all occasional hunters. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. However, the extent of the bias is likely very small since the missing hunters are all occasional hunters and only represent six percent of the total hunter population (Table 10).

Due to the relatively small number of intensive hunters registered in Gjoa Haven, the intensive classification was joined with the active classification for the purpose of calculating harvest estimates.

The HTO Board felt that there were more than eight intensive hunters in the community. Given that all the un-registered hunters identified were occasional hunters it is likely that some intensive hunters were misclassified rather than un-registered. The effect of this should be minimal since, as discussed above, we have joined the active and intensive classifications for the estimate calculations.

Survey coverage and non-response bias:

Response rates although good in most months, were lower in the first few months of the study and in the summer and fall of 1998 (year 3), with five months below 75%. As seen in Table 9 the consistent intentional non-response rate in Gjoa Haven was low, at 0.4%, and was not thought to be a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough during most years to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during the summer and fall of years 1 and 3 of the study since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:

During the community visit it was reported that in following Inuit tradition, hunters do not reveal exact counts of harvests – since it is against tradition to count and report their harvest. It was suggested that some hunters may have underestimated and under-reported their harvest, especially for some species such as birds and small game. Readers should also refer to Section 5.4 for a thorough discussion of this issue.

As seen in the recall period tables, the vast majority of the harvest records in years 1, 4 and 5 were collected within three months of the harvest. In years 2 and 3 there were several months with longer recall periods, however most were still under six months. The ability of a hunter to remember their harvest would tend to decrease as the recall period lengthens suggesting that some measurement error may have occurred where recall periods were longer.

As noted in the comments associated with arctic char, below, there was some commercial harvesting of arctic char during the study. It is thought that some of this commercial harvest may have been reported with the subsistence harvest.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted almost entirely of barren-ground caribou, however some island caribou and even a few Peary caribou were reported during the study. For the purpose of calculating harvest estimates they were combined into one category.
2. **Musk-ox:** Harvest estimates seem low (C.F.). DSD reports the following harvest numbers for musk-ox (DSD MXc):

Year 1	Year 2	Year 3	Year 4	Year 5
n/d	34	n/d	n/d	30

   The above data provided by DSD did not specify whether the hunts were subsistence or sport hunts, however we were informed that there are usually 3 to 5 sport hunts per year. This would indicate that the subsistence harvest for years 2 and 5 should be at least 29 and 25 respectively. These data indicate that harvest estimates in years 2 and 5 appear to be low.
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
4. **Wolf:** Harvest estimates seem a little low (C.F.). Data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 6 wolf pelts were purchased in 1999/2000 (year 4) and 5 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Based on this information the harvest estimate for year 5 does appear low however the estimate for year 4 looks to be in the right range.

[5] **Arctic fox:** Harvest estimates in years 3 and 5 seem too low (C.F.). Again DSD reports were consulted and they showed that 6 pelts were purchased from Gjoa Haven hunters in 1999/2000 (year 4) and 54 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Given the harvest estimates shown it appears that the estimate in year 5 is low.

[6] **Wolverine:** Harvest estimates seem low (C.F.). DSD reports were consulted but did not show any records of pelts purchased in years 4 or 5 (DSD FB).

[7] **Small game:** Hunters indicated that many were not reporting small game harvests to the Fieldworker so estimates seem very low. Many hunters did not think to report these species (C.F.).

[8] **Bearded seal:** In years where 0 were recorded there were likely some caught but not reported (C.F.).

[9] **Geese:** Harvest estimates for snow geese seem accurate. CWS supported hunts in years 4 and 5 resulting in more harvesting during these years. However, estimates for all other waterfowl seem low (C.F.).

[10] **Ptarmigan:** Harvest estimates seem low. Hunters reported that they were not specifically asked how many animals they harvested of each species. They were only asked what they caught. Many hunters did not think to report their small game and bird harvests (C.F.).

[11] **Eggs:** Again, harvest estimates appear low. Large numbers of eggs are gathered each year but again many hunters did not report them to the Fieldworker (C.F.).

[12] **Arctic char:** Harvest estimates seem to be in the right range (C.F.). Hunters reported that there was some commercial fishing early in the study and some may have been reported. There were no records in the database which indicated that the catch was commercial, however some commercial catches may have been reported. DFO records confirm that there was commercial fishing of arctic char during the study (DFO F).

[13] **Lake trout:** The year 1 harvest estimate seems low since there are many trout caught each year in the spring. Estimates in the other years look accurate (C.F.).

[14] **Least cisco:** Harvest estimates seem too low; some are taken every year. It was reported that most people did not record these fish. They are caught in nets and when checking nets there can easily be 50 in one day alone (C.F.).

Although no beluga whales were reported to the Harvest Study Fieldworker, DFO records show a harvest of 3 animals in 1999/2000 (DFO N/B).

6.2.4

6.2.4 Community Results Discussion: Kugaaruk

The survey frame:

An assessment of under-enumeration during the community visit revealed that there were approximately 68 hunters who were not registered in the Harvest Study. Sixty-seven of these were Inuit - 62 occasional and five active hunters. It is estimated that there was one non-Inuit hunter with assigned hunting rights who was not registered – an occasional hunter. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. Given that these unregistered hunters represent forty percent of the total hunter population and that five of the hunters were active hunters (Table 10) the effect of this bias on harvest estimates is likely very significant and could have caused an under-estimation of the community harvest of up to 50%. Harvest estimates for the unregistered hunters can be estimated using mean harvest quantities for each species by strata. However, these estimates, having their own sources of error and bias, are beyond the scope of this Final Report. Readers may apply to NWMB to obtain the results of these calculations.

Survey coverage and non-response bias:

Response rates although good in most months, were lower in year 1, when rates dropped below 50% in a few months, and in the first month of year 2. In years 3 to 5 response rates were high in almost all months, with only the occasional month below 75%. As seen in Table 9 the consistent intentional non-response rate in Kugaaruk was nil, and therefore was not a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough during years 2 to 5, with the exception of the first month in year 2, to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during year 1 and during the first month of year 2 (June 1997) since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:

It was reported during the community consultations that some egg harvests were under-reported. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, years 1, 2 and most of year 5 had short recall periods with the majority of harvest records having been collected within three months of the harvest, minimizing measurement error due to recall failure. However, recall periods were much longer, over six months in many cases, during several months in years 3 and 4. Recall error in these instances is more likely.

As noted in the comments associated with arctic char, below, there was commercial harvesting of char during the study. It appears that harvest estimates do include some of the commercial harvest early in the study and should be considered too high if only considering the subsistence harvest of the community. However, in the latter years of the study harvest estimates are thought to be too low to include both subsistence and commercial harvests.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of both barren-ground caribou and island caribou. Also, some hunters did not specify the type of caribou harvested. For the purpose of calculating harvest estimates they were combined into one category. All harvest estimates appear too low (C.F.).
2. **Musk-ox:** The community was issued 15 tags per year but not all were taken. The HTO Board estimates about 5 per year were used. Although the year 2 estimate seems too low, some others seem a little high. The annual mean appears to be in the right range (C.F.).
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
4. **Tundra grizzly:** The community generally harvests about 1 bear annually, so data from years with no reported harvest may be incorrect (C.F.).

[5] **Wolf:** Harvest estimates seem a little low. Data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 40 wolf pelts were purchased in 1999/2000 (year 4) and 27 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Based on this information the harvest estimates do appear to be low in the last two years of the study.

[6] **Arctic fox:** Again, DSD provided reports for 1999/2000 and 2000/2001 (years 4 and 5) which indicated that 28 arctic fox pelts were purchased in 1999/2000 (year 4) and 48 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Based on this information the harvest estimates may also be somewhat low.

[7] **Seals:** Most of the unidentified seals were likely ringed seals. Harvest estimates may be a little low in some years but are in the right range. However, hunters reported that harbour seals are not hunted by the community and they questioned the report of this harvest in year 4 (C.F).

[8] **Narwhal:** Some of the harvest estimates seem too low (C.F). The community had an annual quota of 10 but had harvested over quota on some occasions. However, there was one year in which no narwhal were harvested, so the data indicating no narwhal harvests in year 4 is accurate. DFO reports the following harvest numbers for narwhal (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DSD N/B):

96/97	97/98	98/99	99/00	00/01
7	15	8	0	30

These data indicate that harvest estimates appear low in four years of the study.

[9] **Snow goose:** Harvest estimates seem low. Approximately 15-20 snow geese are harvested every year (C.F.).

[10] **Canada goose:** As per the snow goose comments above, about 15-20 Canada geese are harvested annually (C.F.).

[11] **Eider duck:** Both king and common eiders are harvested around the community, however neither are very abundant (C.F.).

[12] **Eggs:** Harvest estimates appear too low. Hunters commented that they did not know to report eggs. Eggs are harvested every year; mostly seagull eggs but some goose and eider duck eggs are also gathered (C.F.).

[13] **Arctic char:** Harvest estimates in years 4 and 5 seem too low. Arctic char were fished commercially in about 12 places around the community. It appears that in years 1 and 2 some of these commercially caught fish were reported, whereas estimates in the later years are thought to be too low and not to include commercial fishing (C.F.). DFO records confirm that commercial quotas were issued during each year of the study (DFO F).

[14] **Lake trout:** The HTO Board estimates that the community harvests between 600 and 700 annually. Based on this information estimates in some years may be low (C.F.).

[15] **Sculpin:** The estimate in year 2 seems high, but harvesters often catch them in nets when fishing for other species – they are usually thrown back in the water though (C.F.).

6.2.5 Community Results Discussion: Kugluktuk

The survey frame:

An assessment of under-enumeration during the community visit indicated that there were very few Inuit hunters who were not registered in the Harvest Study. However it is estimated that there was one active hunter and three occasional hunters with assigned hunting rights who were not registered. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. However, the extent of the bias is likely very small since the missing hunters only represent one percent of the total hunter population (Table 10).

There were no intensive hunters registered in Kugluktuk. Harvest estimates were calculated based on two classifications of hunters: occasional and active.

Survey coverage and non-response bias:

Response rates although good in most months, were lower in year 1 and in the first few months of year 2. In years 3 to 5 response rates were high in almost all months, with only the occasional month below 75%. As seen in Table 9 the consistent intentional non-response rate in Kugluktuk was low, at 0.5%, and was not thought to be a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough during years 2 to 5, with the exception of the first few months in year 2, to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during year 1 and the first few months of year 2 (June - August 1997) since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:

It was reported during the community consultations that egg harvests were often under-reported. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, the vast majority of harvest records were collected within three months of the harvest, thereby minimizing recall error.

As noted in the comments relating to arctic char, below, there was commercial fishing of char during the Harvest Study. The Fieldworker reported that most hunters did report their commercial harvests but that she was aware of one hunter in particular who fished commercially for arctic char but who was not on the interview list (this person was not selected during the sub-sampling in this community). Harvest estimates should be considered to include the subsistence harvest and most of the commercial harvest.

There was also one harvest of caribou that was reported to be sold commercially. This entry was removed from the database and can be viewed in Table 4.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of both barren-ground caribou and island caribou. Also, some hunters did not specify the type of caribou harvested. For the purpose of calculating harvest estimates they were combined into one category.
2. **Musk-ox:** Harvest estimates seem too low. The HTO Board estimates that the subsistence harvest was closer to about 40 per year (C.F.). DSD was contacted for more information on quotas and annual harvests. The local Wildlife Officer confirmed that in the three management zones for musk-ox Kugluktuk hunters would usually take at least 40 animals annually for subsistence (DSD MXd).
3. **Moose:** Harvest estimates seem too low. The community reports that hunters usually take between 5 and 7 animals annually (C.F.).
4. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
5. **Tundra grizzly:** Harvest estimates seem to be in the right range. DSD was contacted for more information with regards to the grizzly harvest. They confirmed that the harvest was approximately 3 bears per year over the five years of the Harvest Study.

6 **Wolf:** Harvest estimates seem a little low (C.F.). Wolves tend to be more abundant when there are more caribou around. Readers will note that the highest harvest year for caribou corresponds with higher harvesting of wolves as well. Data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 92 wolf pelts were purchased in 1999/2000 (year 4) and 33 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Based on this information the harvest estimates do appear a little low but are in the right range.

7 **Arctic fox:** Harvest estimates seem a little low (C.F.). Again, DSD provided reports for 1999/2000 and 2000/2001 (years 4 and 5) which indicated that 168 arctic fox pelts were purchased in 1999/2000 (year 4) and 246 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). This information indicates that the harvest estimates for year 4 appear low but that the year 5 estimate may be too high. When both years are considered together harvest estimates appear to be in the right range.

8 **Coloured fox:** Similar to arctic fox, estimates seem to be a little low (C.F.). DSD reports indicate that 196 coloured fox pelts were purchased in 1999/2000 (year 4) and 128 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Both of these figures are higher than harvest estimates and indicate that estimates are likely low.

9 **Muskrat:** Some are taken every year so data from years with little or no harvest seem inaccurate (C.F.).

10 **Wolverine:** Some estimates appear too low. The community reported that they usually harvest about 100 animals annually (C.F.). There is an ongoing monitoring program run by DSD where hunters are paid for their wolverine carcasses. Kugluktuk hunters were very cooperative and it is thought that they submitted 75% to 90% of their harvested carcasses. The number of carcasses collected annually during the Harvest Study varied between 89 and 103 (DSD WV), confirming the communities' estimate of a mean annual harvest of around 100 animals. Given this information it appears that Harvest Study estimates are in the right range in some years but low in others.

11 **Seals:** Most of the unidentified seals were likely ringed seals (C.F.).

12 **Eider duck:** Both king and common eiders are harvested by Kugluktuk hunters (C.F.).

13 **Loons:** Common loons are only seen occasionally, whereas yellow-billed loons are more common to the area. Harvest estimates should reflect this but do not, since common loons are shown to be taken in larger numbers (C.F.).

14 **Sandhill crane:** Harvest estimates seem low. Some are taken every year (C.F.).

15 **Eggs:** Egg harvest estimates look too low in most years for most species. Hunters reported that many people did not realize they were to report their egg harvests (C.F.).

16 **Arctic char:** Harvest estimates look accurate. The HTO Board reports that commercial fishing was done in about four areas during the study (C.F.). DFO records confirm that quotas were issued for experimental fisheries in these areas but did not indicate amounts caught (DFO F). Some commercial harvests were likely reported during the study but not all.

17 **Lake trout:** Harvest estimates seem accurate. The increase in harvesting in year 4 was due to fishing derbies being initiated (C.F.).

18 **Inconnu:** Hunters commented that these fish are not found in the area. They suspect that another fish was harvested that was not on the species list (C.F.).

19 **Cod:** Harvest estimates seem accurate. The increase in harvesting in year 4 was due to fishing derbies being initiated (C.F.).

6.2.6

6.2.6 Community Results Discussion: Taloyoak

The survey frame:
An assessment of under-enumeration during the community visit indicated that there were very few Inuit hunters who were not registered in the Harvest Study. However it is estimated that there were three occasional hunters with assigned hunting rights who were not registered. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. However, the extent of the bias is likely very small since the missing hunters were all occasional hunters and only represent one percent of the total hunter population (Table 10).

Due to the relatively small number of intensive hunters registered in Taloyoak, the intensive classification was joined with the active classification for the purpose of calculating harvest estimates.

Survey coverage and non-response bias:
Response rates in the spring and summer were consistently low throughout the study; however there was some improvement in these rates in the final year. During the community consultation it was reported that hunters were out on the land during these months and very little backfill of data was done when they returned to the community until the final year of the study. Response rates in the spring and summer months were often below 50% and harvest estimates from these months should be used with caution. As seen in Table 9 the consistent intentional non-response rate in Taloyoak was low, at 0.4%, and was not thought to be a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough during most of the fall and winter months in all years to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during the spring and summer since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:
During the community visit hunters reported that when some people were interviewed regarding their arctic char catches – especially in the spring and winter when netting – numbers would be estimated. Hunters would be more likely to underestimate than overestimate which would result in lower than actual harvest estimates. It was also reported during the community consultation that egg harvests were under-reported. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, during most months of the study the majority of harvest records were collected within three months of the harvest. However, there were several months in each year of the study where there was an increase in the percentage of records with recall periods of four to six months. These months should be noted since there is a greater potential for measurement error due to recall failure as recall periods increase.

Commercial quotas for arctic char were issued each year for Lord Lindsay Lake and Agnew River however no catches were reported back to DFO during this period. There were also experimental fishery licences for arctic char, lake trout and whitefish issued. Catches of char from these experimental licences were reported back to DFO in year 1 of the study (DFO F). It appears that some of these catches were likely reported during the study and estimates should be assumed to include the subsistence harvest and some of the commercial harvest.

Some caribou were sold to the local HTO by hunters during the study. These animals are included in the harvest estimates.

Community feedback and other sources of data:
Readers will note that the harvest estimates in year 3 are significantly lower than other years for almost all species. When discussing this issue at the community level, hunters reported that there was not a dramatic decrease in harvesting during that year. Although the reason for this apparent decrease in harvesting was not found, readers should exercise caution when using data from year 3. Almost all estimates are felt to be too low in this year. The comments to follow relate only to the other four years of the study and should also be considered.

1. **Caribou:** Caribou harvesting consisted of both barren-ground caribou and island caribou. Also, some hunters did not specify the type of caribou harvested. For the purpose of calculating harvest estimates they were combined into one category. Harvest estimates in years 4 and 5 appear to be in the right range. Some hunters sell caribou to the local HTO (C.F.).
2. **Musk-ox:** Harvest estimates seem low in all years. The HTO Board estimates that around 25 are harvested each year (C.F.).
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
4. **Arctic fox:** Numbers of fox will vary from year to year, affecting harvest numbers (C.F.). DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 20 arctic fox pelts were purchased in 1999/2000 (year 4) and 6 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). This information suggests that harvest estimates for these years are in the right range.

[5] **Narwhal:** Harvest estimates seem accurate. The community had an annual quota of 10 animals but did not always harvest their full quota (C.F.). DFO reports the following harvest numbers for narwhal (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
0	0	n/d	0	3

[6] **Beluga:** The HTO holds an annual hunt for beluga and charters a plane for this purpose. Usually approximately 17-20 animals are harvested during this hunt (C.F.). Based in this information harvest estimates seem low in all years but year 4. Hunters reported that belugas were harvested in year 1 and data indicating no reported harvests seems inaccurate. DFO reports the following harvest numbers for beluga (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
15	n/d	n/d	n/d	22

[7] **Geese:** All harvest estimates seem too low. Most harvesting takes place from mid-May to the 1st week of July. Harvesters were out on the land and not reporting. It was during this period each year where response rates in Taloyoak declined for this reason. Hunters report that estimates for all types of geese are too low but primary harvesting is of snow geese and Canada geese. There is a major nesting site for snow geese near the community in the Marcheson River area; many are harvested here (C.F.).

[8] **Eider duck:** Both king and common eiders are harvested in the area. Although they have been less abundant in recent years, harvest estimates still appear to be too low in some years (C.F.).

[9] **Tundra swan:** There are always some harvested each year so the three years with no reported harvests are misleading. However, in year 3 it is unlikely that 88 were harvested, this estimate seems too high (C.F.).

[10] **Eggs:** Harvest estimates appear to be too low in all years. Harvesters collect a large number of eggs each year. Many hunters did not report their eggs. Some reasons were suggested to explain why, including that hunters may not have been specifically asked about their egg harvests or that they did not count their eggs so found it too difficult to estimate and report after the fact (C.F.).

[11] **Arctic char:** Harvest estimates seem to be in the right range except in year 3 when estimates seem much too low (C.F.). There is commercial fishing for arctic char around the community. Harvest estimates likely include these commercial harvests. Commercial quotas were issued each year for Lord Lindsay Lake and Agnew River however no catches were reported back to DFO during this period. There were also experimental fishery licences issued (DFO F).

[12] **Cod:** Hunters report that they are abundant around the community and some are harvested each year (C.F.).

6.2.7

6.2.7 Community Results Discussion: Umingmaktok

The survey frame:
An assessment of under-enumeration indicated that there were very few hunters who were not registered in the Harvest Study.

The population of Umingmaktok declined over the course of the Harvest Study resulting in very low numbers of active hunters registered by the end of the study. There were no intensive hunters registered. The occasional and active classifications were joined and harvest estimates were calculated for all hunters together; there was no stratification used.

Survey coverage and non-response bias:
Response rates were very good to excellent in all years except for the last five months of year 5 where rates fell below 75% due to Fieldworker staffing difficulties. Readers should exercise caution when using the data collected during these final five months. As seen in Table 9 the consistent intentional non-response rate in Umingmaktok was nil and therefore was not a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough during years 1 to 4 to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during the latter months of the study (January – May 2001) since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:
As seen in the recall period tables, the vast majority of harvest records were collected within three months of the harvest. However, long recall periods of over six months were encountered during the last few months of the study. This was due to Fieldworker staffing difficulties. Recall error in these instances is more likely.

During the time of the community visits held in the Kitikmeot region in the winter of 2003 most hunters from Umingmaktok were living in other communities and the HTO was not active. It was not possible to hold consultations on the data. Readers will note that there is a steady decline in harvest estimates during the study. This is likely an accurate change and due to the decline in the population of this community over the five years of the study. The number of hunters registered declined from 31 to 11 over this period, a drop of over 60%.

6.3 Kivalliq Region

6.3.1 Community Results Discussion: Arviat

The survey frame:
An assessment of under-enumeration during the community visit indicated that there were very few Inuit hunters who were not registered in the Harvest Study. It is estimated that there were five non-Inuit hunters with assigned hunting rights who were not registered, all occasional hunters. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. However, the extent of the bias is likely very small since the missing hunters only represent one percent of the total hunter population (Table 10).

Due to the relatively small number of intensive hunters registered in Arviat, the intensive classification was joined with the active classification for the purpose of calculating harvest estimates.

Survey coverage and non-response bias:
Response rates remained high throughout the course of the Harvest Study. Non-response bias was felt to be minimal. As seen in Table 9 the consistent intentional non-response rate in Arviat was low, at 0.3%, and was not thought to be a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough in all years to ensure that n did in fact constitute a sufficiently representative sample of N hunters.

Measurement issues and response error:
It was reported during the community consultations that egg harvests were under-reported. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, the vast majority of harvest records were collected within three months of the harvest, thereby minimizing recall error.

There was commercial harvesting of arctic char during the Harvest Study. As seen below in the comments relating to the char harvest, some of the commercial harvest was reported along with the subsistence harvest. Other harvest records indicated that they were commercial and were removed from the database; these can be seen in Table 4.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of barren-ground caribou.
2. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
3. **Tundra grizzly:** Harvest estimates seem to be in the right range. Arviat shared a quota of 5 animals with Rankin Inlet, Chesterfield Inlet and Whale Cove. Years with no reported harvest may be inaccurate; however the year 4 estimate of 4 may be high (C.F.).
4. **Arctic fox:** Almost all furs are sold, so in order to verify harvest estimates data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 441 arctic fox pelts were purchased in 1999/2000 (year 4) and 916 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). The harvest estimate for year 4 appears to be low whereas that for year 5 looks to be accurate.

[5] **Wolverine:** The harvest estimate for year 3 seems too high. However, the mean of 9 per year was thought to be accurate (C.F.).

[6] **Ringed seal:** Sampling took place from hunter's catches in the fall of 1998, 1999 and 2000 (Cleator, 2001). This may explain the higher numbers during these years. The mean harvest over the five years of the study looks accurate (C.F.).

[7] **Harbour seal:** In years where 0 were recorded there were likely some caught but not reported (C.F.).

[8] **Walrus:** It is suspected that some walrus were not reported; hunters harvest walrus every year but need to travel to the Rankin Inlet area to do so (C.F.).

[9] **Beluga:** The harvest estimate in year 2 seems too high (C.F.). DFO reports the following harvest numbers for beluga (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
100	100	9	58	100

[10] **Snow goose:** Harvest estimates seem a little low; the mean harvest should be closer to about 1800 to 2000 per year (C.F.).

[11] **Eggs:** Harvest estimates for eggs seem low. It is suspected that hunters were either not reporting eggs or were not counting them and under-estimating how many were gathered. It was also reported during the community visit that hunters do not normally separate out the different types of eggs gathered so the reported species of eggs may not be accurate. Both arctic tern eggs and black guillemot eggs are harvested in large numbers by Arviat residents, however very few were reported during the Harvest Study (C.F.).

[12] **Arctic char:** There was some commercial harvest of arctic char during the Harvest Study (DFO F). In assessing the harvest estimates it was thought that the estimates would represent the subsistence harvest and some of the commercial char harvest (C.F.). The Harvest Study Fieldworker reported that most hunters did report their commercial harvest and that some of this harvest would have been sold locally to stores or individuals in Arviat.

[13] **Lake trout/cod:** Many of the trout and cod reported during the Harvest Study were caught during fishing derbies. Towards the beginning of the study there were lake trout derbies and in the last few years there were cod derbies held (C.F.).

[14] **Arctic grayling:** Higher estimates in years 1 to 3 may have been due to lake trout derbies. Hunters may have caught grayling when fishing for trout (C.F.).

Some species were not reported during the Harvest Study but were harvested by Arviat hunters. The community reports that narwhal were harvested but not reported. Arviat hunters did not have a quota for narwhal but they reported that tags were obtained from other communities for this harvest. However, we were unable to obtain records on the number of narwhal taken during the study. Mussels were also harvested during the study but not reported.

6.3.2 Community Results Discussion: Baker Lake

The survey frame:

An assessment of under-enumeration during the community visit revealed that there were approximately 67 hunters who were not registered in the Harvest Study. Sixty-five of these were Inuit, all occasional hunters. It is estimated that there were two non-Inuit with assigned hunting rights who were not registered – one occasional and one active hunter. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. Given that these unregistered hunters represent 16 percent of the total hunter population (Table 10) the effect of this bias on harvest estimates could be significant. Harvest estimates for the unregistered hunters can be estimated using mean harvest quantities for each species by strata. However, these estimates, having their own sources of error and bias, are beyond the scope of this Final Report. Readers may apply to NWMB to obtain the results of these calculations.

Due to the relatively small number of intensive hunters registered in Baker Lake, the intensive classification was joined with the active classification for the purpose of calculating harvest estimates.

Survey coverage and non-response bias:

Response rates in year 1 were very good but then began to decline rapidly. Originally one of the sub-sampled communities, due to declining response rates in Baker Lake, all occasional hunters not previously on the interview list were added to this list in year 3. Unfortunately rates continued to fall throughout the study and readers should consider this when using harvest data from this community. During the community visit it was reported that low response rates were due in part to high Fieldworker turnover and conflicts with the Nunavut Hunter Support Program. As seen in Table 9 the consistent intentional non-response rate in Baker Lake was high, at 32.7%, resulting in a high potential for non-response bias.

Response rates were felt to be high enough and non-response bias low enough during year 1 to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Unfortunately due to declining response rates and increasing intentional non-response the same cannot be said for the other years of the study. Readers should exercise caution when using the data collected during years 2 to 5 of the study since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:

There were no specific incidents of measurement error brought up during the community visit. However, readers should refer to Section 5.4 for a thorough discussion of this issue.

As seen in the recall period tables, during the first three years of the study recall periods were high, often over six months. This calls into question the ability of hunters to accurately remember what they had harvested and may have resulted in some measurement error. Recall periods did improve in the last two years of the study when over 75% of the records were collected within three months of the harvest.

Commercial quotas were issued by DFO for whitefish, lake trout and arctic char during the Harvest Study. A small number of char were reported caught and no harvests of whitefish or lake trout were reported back to DFO (DFO F). It is unlikely that harvest estimates contain a large number of commercially harvested fish.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of barren-ground caribou. Harvest estimates from years 3 to 5 seem low (C.F.).
2. **Musk-ox:** Baker Lake had an annual quota of 19 animals. The community reports that only approximately 8 of those tags were used per year since hunters must travel large distances to harvest musk-ox (C.F.).
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).

[4] **Tundra grizzly:** At least 1 to 2 per year are harvested. In years when 0 were recorded some were likely caught but not reported (C.F.). DSD staff confirmed that the annual quota for grizzlies was 5 animals and that the community usually harvests about 3 bears per year.

[5] **Wolf:** With the exception of the year 3 harvest estimates, all estimates seem too low. The mean annual harvest should be closer to 150 animals (C.F.). DSD reports indicate that 124 wolf pelts were purchased from Baker Lake hunters in 1999/2000 (year 4) and 44 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB).

[6] **Arctic fox:** Harvest estimates for years 3 to 5 seem too low (C.F.). This was confirmed for the last two years by DSD reports indicating that 312 arctic fox pelts were purchased from Baker Lake hunters in 1999/2000 (year 4) and 92 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB).

[7] **Coloured fox:** In years where 0 were recorded, there were likely some harvested but not reported (C.F.).

[8] **Ringed seal:** The Baker Lake HTO Board reports that every few years, 2 to 3 ringed seals are harvested. They feel that there were a small number of seals harvested in year 5 that were not reported (C.F.).

[9] **Snow goose:** All harvest estimates seem too low. The HTO Board reports that approximately 150 are harvested each year (C.F.).

[10] **Canada goose:** They are less abundant than snow geese. The year 1 estimate seems accurate whereas the estimates in the other years seem low. The HTO Board reports that approximately 75 are harvested each year (C.F.).

[11] **Eggs:** All harvest estimates for eggs appear too low. Many hunters did not report their egg harvests. Eggs gathered in the area include snow goose eggs (approximately 200 per year), Canada goose eggs (approximately 150 per year) and occasionally seagull eggs (approximately 30 per year) (C.F.).

[12] **Arctic char:** Harvest estimates in years 2 to 5 seem too low. The year 1 estimate of 1157 appears to be more accurate (C.F.).

[13] **Arctic grayling:** These fish are abundant in the area; some are caught every year (C.F.).

[14] **Whitefish:** Harvest estimates seem too low. Estimates should be close but not quite as high as lake trout estimates (C.F.).

6.3.3 Community Results Discussion: Chesterfield Inlet

The survey frame:
An assessment of under-enumeration during the community visit revealed that there were approximately 14 hunters who were not registered in the Harvest Study. Twelve of these were Inuit, all were occasional hunters. It is estimated that there were two non-Inuit with assigned hunting rights who were not registered, both also occasional hunters. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. Given that these unregistered hunters represent 13 percent of the total hunter population (Table 10) the effect of this bias on harvest estimates could be significant. However, the effect would be lessened by the fact that all unregistered hunters were thought to be occasional hunters. Harvest estimates for the unregistered hunters can be estimated using mean harvest quantities for each species by strata. These estimates, having their own sources of error and bias, are beyond the scope of this Final Report. Readers may apply to NWMB to obtain the results of these calculations.

Survey coverage and non-response bias:
In general response rates were relatively high throughout the study. However, there were some months with lower (more problematic) response rates. Also the response rates of the intensive hunters were lower than the other two strata in many months. As seen in Table 9 the consistent intentional non-response rate in Chesterfield Inlet was relatively high, at 5.4%, and there may be potential non-response bias as a result.

Response rates were felt to be high enough and non-response bias low enough during most months of the study to ensure that N did in fact constitute a sufficiently representative sample of N hunters. Readers should refer to the response rate tables when using the harvest estimates provided and exercise caution when using the data collected during months with lower response rates since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:
It was reported during the community consultations that egg harvests were under-reported. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, the vast majority of harvest records were collected within three months of the harvest, thereby minimizing recall error. The only exceptions were November and December 1998 (year 3) when all records were collected four to six months after the harvest.

During the Harvest Study there may have been some commercial harvests of char and of caribou. Although some of these harvests may have been reported with the subsistence harvest (see notes for caribou below), this was thought to be rare and harvest estimates should be viewed as the subsistence harvest only.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of barren-ground caribou. Harvest estimates in years 3, 4 and 5 seem low. However, in the first two years of the study hunters reported that there were tags available for the commercial harvest of caribou and some were harvested for the meat plant (C.F.).
2. **Musk-ox:** Harvest estimates are suggested not to be accurate in years with no harvest reported. The community had an annual quota of 5 animals and although they did not always use all the tags they report that most were taken each year (C.F.). The local Wildlife Officer confirmed this statement.
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
4. **Wolf:** The harvest estimate in year 1 seems too low (C.F.).
5. **Ringed seal:** DFO were collecting ringed seal samples from hunters from 1999 to 2001; 112 samples were submitted by Chesterfield Inlet hunters over this period (Cleator, 2001).
6. **Harp seal:** No harvests were reported in year 5. However, hunters report that there has been in increase in numbers and some would have been taken during this year (C.F.).
7. **Harbour seal:** Similar to the harp seals, hunters reported that some would have been harvested in the last year of the study (C.F.).

[8] **Walrus:** Harvest estimates appear too low in years 2 and 3. The annual mean harvest is said to be about 4 per year (C.F.).

[9] **Narwhal:** There was some doubt that there were no harvests of narwhal in year 4. However, the harvest estimates in other years were thought to be in the right range (C.F.). DFO reports the following harvest numbers for narwhal (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
0	0	3	5	3

[10] **Beluga:** The harvest estimate in year 5 seems low (C.F.). DFO reports the following harvest numbers for beluga (note that DFO data are based on fiscal years, whereas Harvest Study data are based on years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
20	n/d	15	n/d	1

[11] **Snow goose:** Harvest estimates in years 4 and 5 seem low. The community reports that they harvest at least 10 to 20 per year (C.F.).

[12] **Canada goose:** The harvest estimate for Canada geese in year 4 also looks low (C.F.).

[13] **Eggs:** The HTO Board reported that people did not count their eggs and did not report them – harvest estimates for almost all eggs seem too low. *Goose eggs:* Some are collected every year, data from years with no harvest are inaccurate and harvest estimates in other years look low. *Duck eggs:* The harvest estimate in year 2 appears to be in the right range but all others seem too low. *Arctic tern eggs:* Harvest estimates appear low; a harvest of over 100 per year would be more accurate. S*eagull eggs:* Harvest estimates seem low; an estimate approximately 100 per year would be reasonable. *Black guillemot eggs:* Harvest estimates should be about 50-60 per year (C.F.).

[14] **Arctic char:** Harvest estimates in years 3 and 4 seem low. Estimates from other years appear more accurate (C.F.).

[15] **Lake trout:** Lake trout are harvested during fishing derbies and some are caught in nets when fishing for arctic char. Estimates for the last three years of the study were reported to look low (C.F.).

[16] **Burbot:** Similar to the lake trout, burbot are caught both during fishing derbies and in arctic char nets. The estimate in year 4, the only year in which they were reported, looks accurate but there should have been similar harvests reported each year (C.F.).

[17] **Cod:** It was reported that cod are caught every year (C.F.).

6.3.4 Community Results Discussion: Coral Harbour

The survey frame:
An assessment of under-enumeration during the community visit indicated that there were very few hunters who were not registered in the Harvest Study. It is estimated that there were five non-Inuit hunters with assigned hunting rights, all occasional hunters. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. However, the extent of the bias is likely very small since the missing hunters only represent two percent of the total hunter population (Table 10).

Survey coverage and non-response bias:
Response rates were low in several months in each year of the study with the exception of year 5 when response rates were relatively high. Data from years 2 to 4 should be used with caution since rates dropped below 50% in many of these months, some dropping as low as 14%. As seen in Table 9 the consistent intentional non-response rate in Coral Harbour was moderate, at 4.6%, and there is a potential for non-response bias as a result. Given this and the low response rates in many years of the study, the potential for both sampling error and non-response bias is high in some months of the study.

Response rates were felt to be high enough and non-response bias low enough during year 5 to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected in the other years.

Measurement issues and response error:
It was reported during the community visit that some hunters did not keep track of the number of eggs harvested. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, problems with long recall periods were encountered in some years, particularly years 2, 3 and 4. During the course of the study 24% of the harvest records had recall periods of over six months. This calls into question the ability of hunters to accurately remember what they had harvested and may have resulted in some measurement error.

As indicated in the comments below, there is an annual commercial caribou harvest. The Harvest Study did not collect information on these commercial harvests. Although some hunters may have included a commercial harvest along with their subsistence harvest this was thought to be rare and harvest estimates should be viewed as the subsistence harvest only.

DFO issued licences for commercial harvests of arctic char from Duke of York Bay and from Cleveland River; however no catch data were reported (DFO F). The harvest estimates for arctic char should also be viewed as the subsistence harvest only.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of barren-ground caribou. There was a commercial harvest of caribou each year in Coral Harbour but very few of these were thought to be reported during the Harvest Study. Harvest estimates displayed in the tables represent the subsistence harvest of the community and seem accurate (C.F.).
2. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
3. **Wolf:** The harvest estimate of 15 in year 3 seems too high. A wolf pack came over in 1998/99 and each year since then at least one is harvested (C.F.).
4. **Arctic fox:** Harvest estimates seem low (C.F.). Almost all furs are sold, so in order to verify harvest estimates, data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 1056 arctic fox pelts were purchased from Coral Harbour hunters in 1999/2000 (year 4) and 1880 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Both of these numbers exceed the harvest estimates confirming that estimates are likely low.
5. **Arctic hare:** Harvest estimates seem too low. Some are harvested every year, so in year 4 when none were reported there were likely some hares taken (C.F.).
6. **Harp seal:** It appears that some harp seal harvests were not reported; hunters harvest harp seals every year. The harvest estimate in year 2 seems accurate (C.F.).
7. **Walrus:** The annual quota was 60 animals, but all tags were not always used. A mean harvest of about 19 animals as displayed is in the right range. It was suggested however, that the harvest estimates in the first few years seem low since there was more harvesting of walrus then (C.F.).
8. **Beluga:** The community considers the harvest estimates to be in the right range; the average harvest seems accurate (C.F.). However, DFO reports the following, much lower, harvest numbers for beluga (note that DFO data are based on fiscal years, whereas Harvest Study data are based on years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
31	30	25	50	38

[9] **Canada goose/snow goose:** Some harvest estimates seem too low. In general hunters harvest about 1 Canada goose to every 5 snow geese. Snow goose estimates were thought to be in the right range but Canada goose estimates appear to be quite low. It is possible that many of the unidentified geese harvested were actually Canada geese (C.F.).

[10] **White-fronted goose:** Similarly to the Canada geese, the harvest estimates of white-fronted geese seem too low. The community estimates that on average about 1000 are harvested each year (C.F.).

[11] **Eider duck:** Both king eider and common eiders are harvested, but common eiders are harvested in larger numbers. Harvest estimates seem low; the community feels that a more accurate estimate would be between 70 and 80 per year (C.F.).

[12] **Eggs:** Hunters do not count the eggs they gather. They may get one box but they do not count how many are in the box. Most hunters when interviewed would need to either estimate their harvest or would often not report their eggs. Harvest estimates seem low. The majority of eggs collected were snow goose eggs; harvest estimates should be higher than the number of geese harvested. There was also some harvesting of eider duck eggs and seagull eggs. These harvest estimates also appear low in the data tables (C.F.).

[13] **Eider down:** People have not kept track of the down they have harvested; estimates are too low. Some down was harvested each year. One person easily collects 2 to 3 bags of down and each bag could contain the down of over 80 nests (C.F.).

[14] **Arctic char:** Harvest estimated for char increased in year 4 since a bridge was built that made fishing areas more accessible. Fishing derbies occur annually. No commercial harvesting of char occurred during the Harvest Study. Total char numbers look fairly accurate (C.F.).

[15] **Lake trout:** Harvest estimates look to be in the right range but years 2 and 4 may be a little low. However, fishing derbies do not occur every year for trout and these years may have been without trout derbies. Weather influences whether or not there is a derby since harvesters need to go far to get to the trout lakes (C.F.).

[16] **Cod:** Harvest estimates look very low; there are cod derbies every year. It is assumed that hunters did not report their cod catch. Estimates in the range of 1000 would be more accurate (C.F.).

[17] **Sculpin:** Harvest estimates are very low for sculpin as well. For every cod caught there are probably 2-3 sculpin caught, so a catch of a few 1000 per year would be more accurate (C.F.).

[18] **Mussels:** Harvest estimates are much too low. Many are taken each year. For example in 2002 during Hamlet days the community harvested 14,000 in one day. Most are harvested by women and children; everyone eats them (C.F.).

No narwhal were reported during the study but the community had a quota of 10 whales annually and there were some harvested by Coral Harbour hunters. DFO reports the following harvest numbers for narwhal (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
10	9	4	0	0

Similarly, turbot are harvested by the community and none were reported during the study (C.F.).

6.3.5 Community Results Discussion: Rankin Inlet

Although data collection in most communities began in July 1996, in Rankin Inlet delays were encountered and data collection began one month late in August 1996. Further problems encountered during data collection resulted in missing data from September 1997 to February 1998. In April 2001, a letter was written to the Nunavut Implementation Panel and cc'ed to the relevant RWOs and HTOs informing them of the missing data. The letter also demonstrated the NWMB's approach to the problem, detailing the use of collected data to estimate for the missing months. The Nunavut Implementation Panel accepted the NWMB's approach to the issue in June 2001. As such, there are no data (n/d) displayed for the months in which no data were collected in Rankin Inlet. In order to estimate the total yearly harvest in years 1 and 2, estimates for the missing months were obtained by calculating the mean harvest for the corresponding months in the four years in which data were collected.

The survey frame:
An assessment of under-enumeration during the community visit indicated that there were very few Inuit hunters who were not registered in the Harvest Study. It is estimated that there were 13 non-Inuit hunters with assigned hunting rights who were not registered – all occasional hunters. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. However, the extent of the bias is likely very small since the missing hunters only represent three percent of the total hunter population (Table 10).

Survey coverage and non-response bias:
Response rates were generally very good in the first three years of the study (with the exception of the months in which no data were collected). In the final two years of the study response rates began to fall in some months with rates dropping below 75% in the final months of the study. As seen in Table 9 the consistent intentional non-response rate in Rankin Inlet was high, at 14.8%, resulting in a high potential for non-response bias. Given this and the low response rates in the final two years of the study, the potential for both sampling error and non-response bias is high.

Response rates were felt to be high enough and non-response bias low enough during years 1 to 3 (with the exception of the months in which no data were collected) to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during the last two years of the study.

Measurement issues and response error:
It was reported during the community visit that some hunters did not keep track of the number of eggs harvested. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, most months in years 3 and 5 had short recall periods with the majority of harvest records having been collected within three months of the harvest, minimizing measurement error due to recall failure. However, recall periods were much longer, over six months in some cases, during some months in year 1, year 2 and several months in year 4. Recall error in these instances is more likely.

Records provided by DFO confirm that commercial quotas were issued for arctic char throughout the Harvest Study (DFO F). However, as indicated in the comments relating to arctic char, very few of these harvests were reported during the study. It is also evident when assessing the quantities of char reported by hunters that the vast majority of harvests were for subsistence and not for commercial sale.

Although there is not a large scale commercial harvest of caribou in Rankin Inlet, some animals are sold commercially to the local meat plant. These animals were designated as such in the database, and were later removed and do not make up part of the harvest estimates shown in the data tables.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of barren-ground caribou. The harvest estimate in year 5 seems too low; it was reported that the estimate in year 4 looked more typical and accurate (C.F.). Some caribou were harvested and sold to the local meat plant. These entries were removed from the database and can be viewed in Table 4.
2. **Musk-ox:** The annual quota was 5 animals; however, they were not always all taken. Hunters travel large distances to harvest musk-ox (C.F.).

[3] **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).

[4] **Wolf:** Harvest estimates seem too low, especially in year 5 when none were reported. There are wolves harvested every year (C.F.). In order to verify harvest estimates, data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 62 wolf pelts were purchased from Rankin Inlet hunters in 1999/2000 (year 4) and 25 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Both of these numbers exceed the harvest estimates confirming that estimates are low in these years.

[5] **Arctic fox:** Similarly, arctic fox are harvested every year and the data indicating no harvests reported in year 5 seems inaccurate (C.F.). Again DSD records were consulted for 1999/2000 and 2000/2001 (years 4 and 5) and revealed that 175 arctic fox pelts were purchased from Rankin Inlet hunters in 1999/2000 (year 4) and 107 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Both of these numbers exceed the harvest estimates confirming that estimates are low in these years.

[6] **Wolverine:** Hunters report that wolverines are harvested every year and data from years with no reported harvests appear inaccurate (C.F.). There were no records of wolverine pelts purchased from hunters by DSD (DSD FB) however DSD staff confirms yearly harvests of wolverine of up to 15 animals.

[7] **Arctic hare:** Although harvesting of hare has declined over the years it was reported that some are taken every year (C.F.).

[8] **Seals:** The seal harvest consisted of both ringed seal and bearded seal. Seals (unspecified) would be one of these two species. Harvest estimates seem accurate (C.F.).

[9] **Narwhal:** Hunters travel to the Repulse Bay area to harvest Narwhal. DFO reports the following harvest numbers for narwhal (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
7	0	2	2	7

[10] **Beluga:** DFO reports the following harvest numbers for beluga (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
48	48	35	n/d	45

[11] **Ptarmigan:** Although harvesting changes from year to year due to changes in abundance in the area, some are harvested every year (C.F.).

[12] **Eggs:** Nesting areas are not abundant in the area, eggs are difficult to find but people do harvest some every year. Occasionally some people harvest snow geese eggs from around the Arviat area. They also harvest some arctic tern eggs (none reported). It was reported that all egg numbers seem low since many people do not count their eggs and therefore did not report them (C.F.).

[13] **Arctic char:** There was some commercial fishing of arctic char throughout the study (DFO F). However, it is felt that much of it was not reported. There were a few entries in the Harvest Study database which indicated that the harvest was commercial. These were removed from the database and can be viewed in Table 4. Harvest estimates are thought to be fairly accurate for subsistence harvesting only (C.F.).

6.3.6 Community Results Discussion: Repulse Bay

The survey frame:
An assessment of under-enumeration during the community visit revealed that there were approximately 39 Inuit hunters who were not registered in the Harvest Study, 31 occasional and eight active hunters. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. Given that these unregistered hunters represent 18 percent of the total hunter population (Table 10) the effect of this bias on harvest estimates could be significant. However, the effect would be lessened by the fact that, as reported by the Fieldworker, many of these hunters may have reported their harvest through a family member. Harvest estimates for the unregistered hunters can be estimated using mean harvest quantities for each species by strata. However, these estimates, having their own sources of error and bias, are beyond the scope of this Final Report. Readers may apply to NWMB to obtain the results of these calculations.

Due to the relatively small number of intensive hunters registered in Repulse Bay, the intensive classification was joined with the active classification for the purpose of calculating harvest estimates.

Survey coverage and non-response bias:
Response rates in the first two months of the study (June and July 1996) were low, below 75%, and data from these months should be used with caution. However, rates in the subsequent months of year 1 and in all other years are very good. As seen in Table 9 the consistent intentional non-response rate in Repulse Bay was low, at 0.6%, and was not thought to be a potential source of non-response bias.

An examination of the consistency of participation rates (code 1 response as a proportion of code 1 plus code 2 responses) over a five year period was done in order to detect hidden non-response. The basis for this is that declining rates of harvesting (code 1) might indicate "hunter fatigue" with the survey over time. The community of Repulse Bay did show a noticeable decline in participation over the life of the survey indicating that hidden non-response may have occurred in this community.

Although some hidden non-response bias may have occurred towards the end of the study, given the high response rates during all but the first two months, it was concluded that n did in fact constitute a sufficiently representative sample of N hunters.

Measurement issues and response error:
Although it is felt that most hunters were interviewed during the course of the Harvest Study, as demonstrated by the high response rates, it was suggested during the community visit that some hunters may not have reported all their harvest. We were informed that if hunters did not record their harvest in their calendar they would need to estimate their harvest at the time of the interview. Inuit hunters are more likely to underestimate their catch resulting in lower harvest estimates. Hunters reported during the community visit that interest in the study declined in the latter years and as a result some hunters did not record their harvests as diligently. As seen in the discussion below, the community felt that some estimates were low. These measurement errors are suspected to have played a role in this, however the community agreed that most of the estimates are not seriously wrong and are in the right range.

As seen in the recall period tables, the vast majority of harvest records were collected within three months of the harvest, thereby minimizing recall error. However, as noted above there appears to have been some recall error despite the shorter recall periods.

As indicated in the comments relating to arctic char, below, some of the char harvests were sold commercially to local groups. These data are included within the harvest estimates given that the fish were sold (and most likely consumed) locally.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of barren-ground caribou.
2. **Musk-ox:** Hunters must travel far to harvest musk-ox so few are taken. However, it was reported that hunters travel to the Kitikmeot region for musk-ox and it is suspected that more than one was taken during the Harvest Study (C.F.). The Wildlife Officer confirmed that although the annual quota was 5 animals, the community usually only harvested an average of 1 per year for the reasons mentioned above.
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
4. **Wolf:** Hunters reported that harvest estimates seemed to be in the right range (C.F.). For further verification, data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 58 wolf pelts were purchased in 1999/2000 (year 4) and 64 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). The harvest estimate for years 4 and 5 appear to be somewhat low based on this information.

[5] **Arctic fox:** The harvest estimates for arctic fox seemed to be close to the actual harvest numbers according to hunters (C.F.). Verification of DSD reports did show that the estimates are likely a little low given that 133 arctic fox pelts were purchased from Repulse Bay hunters in 1999/2000 (year 4) and 256 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB).

[6] **Narwhal:** Harvest estimates in years 4 and 5 seem too low. The community was harvesting under a community-based management program since 1999, during which the HTO kept track of the number of animals taken (C.F.). Prior to this program the annual quota was 25 animals. DFO reports the following harvest numbers for narwhal (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
10	35	18	156	49

[7] **Beluga:** Harvest estimates seem accurate (C.F.). DFO reports the following harvest numbers for beluga (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
20	n/d	8	4	10

[8] **Eider duck:** Harvest estimates seem too low. Both king and common eiders are harvested around Repulse Bay (C.F.).

[9] **Eggs:** All harvest estimates for eggs seem too low. It appears that most hunters did not report their egg harvests (C.F.).

[10] **Arctic char:** There was some commercial harvesting of arctic char during the study (DFO F); however most of the fish were sold locally to the HTO and Coop. These harvests were reported along with the subsistence harvest and are included in the harvest estimates shown in the data tables. It was reported that in some years the HTO and Coop store bought less fish from local hunters and this may explain the drop in the harvest estimate in year 5 (C.F.).

6.3.7 Community Results Discussion: Whale Cove

The survey frame:
An assessment of under-enumeration during the community visit revealed that there were approximately 45 hunters who were not registered in the Harvest Study. Forty-four of these were Inuit, all occasional hunters, while one was a non-Inuit with assigned hunting rights, also an occasional hunter. Many of the unregistered hunters were women. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. Given that these unregistered hunters represent 42 percent of the total hunter population (Table 10) the effect of this bias on harvest estimates is likely very significant and could have caused an under-estimation of the community harvest of up to about 40%. Harvest estimates for the unregistered hunters can be estimated using mean harvest quantities for each species by strata. However, these estimates, having their own sources of error and bias, are beyond the scope of this Final Report. Readers may apply to NWMB to obtain the results of these calculations.

Due to the relatively small number of intensive hunters registered in Whale Cove, the intensive classification was joined with the active classification for the purpose of calculating harvest estimates.

Survey coverage and non-response bias:
Overall response rates for hunters from Whale Cove were good in most years of the Harvest Study. There were select months in each year where rates did decline which can be seen in the response rate tables. However, when response rates were calculated separately for the occasional and active hunters, rates were found to be low for the active classification in the last two years of the study. Although rates rarely fell below 50%, readers should consider this information when using harvest estimates from years 4 and 5.

As seen in Table 9 the consistent intentional non-response rate in Whale Cove was moderate, at 4.9%, and there is some potential for non-response bias as a result. Given this and the low response rates particularly of active hunters in final two years of the study, the potential for both sampling error and non-response bias is high in some months of the study and appropriate cautions should be used with these data.

Measurement issues and response error:
It was reported during the community consultations that some harvests, such as eggs and mussels were under-reported. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, during the first year of the study the vast majority of the harvest records were collected within three months of the harvest. However, as the study progressed, recall periods became much longer as seen by the high percentage of records collected at least six months beyond the harvest date. This calls into question the ability of hunters to accurately remember what they had harvested and may have resulted in some measurement error.

As is discussed in the comments relating to arctic char, below, some char harvests were sold to the fish plant in Rankin Inlet throughout the study. It is felt that many of these commercial harvests were reported and would be included in the harvest estimates contained in the data tables.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of barren-ground caribou. Harvest estimates seem accurate (C.F.).
2. **Musk-ox:** The community had an annual quota of 5 animals, but not all were taken each year. However, hunters did recall that at least 2 were harvested in year 5, indicating that although none were reported some were likely harvested (C.F.).
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
4. **Arctic fox:** No arctic fox harvests were reported in year 2; however hunters report that foxes were harvested each year (C.F.).
5. **Arctic hare:** The higher harvest estimate in year 1 was likely due to a contest held that year (C.F.).
6. **Harp seal:** Hunters reported that they take approximately 1 to 2 per year and that the harvest estimate in year 2 seems too high (C.F.).
7. **Narwhal:** DFO reports the following harvest numbers for narwhal (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
0	1	0	2	0

[8] **Beluga:** Hunters reported that they recall more harvesting in years 3 and 4 and that they suspected that harvest estimates are in the right range. They also stated that fewer were harvested in year 5 because of an over-harvest in the previous years (C.F.). DFO reports the following harvest numbers for beluga (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DFO N/B):

96/97	97/98	98/99	99/00	00/01
35	20	25	n/d	20

[9] **Eider duck:** Although few are harvested around the community it was reported that estimates should have been a little higher (C.F.).

[10] **Eggs:** Eggs are collected every year. Although there were no eggs reported in years 1 and 2, many were harvested. Most of the eggs are gathered by women (C.F.). Many of the women of Whale Cove were not registered in the Harvest Study which may account for the low estimates. Hunters also reported that many hunters did not realize they were to report their egg harvests. Eggs that are gathered in the Whale Cove area are as follows (the HTO Board also provided an estimate of the numbers harvested annually): *Goose eggs:* The year 4 and 5 estimates seem to be in the right range. *Duck eggs:* The year 4 estimate is in the right range, few are harvested. *Seagull eggs:* Approximately 50 or so are taken each year. *Arctic tern eggs:* Approximately 10-12 are harvested annually. *Black guillemot eggs:* Approximately 50 or so are taken each year (C.F.).

[11] **Arctic char:** The harvest estimate in year 2 seems low. The HTO Board reported that hunters did sell some of their catch to the fish plant in Rankin Inlet. Harvest estimates may contain some of these commercially sold fish (C.F.).

[12] **Arctic grayling:** Harvest estimates seem much too low. They are often caught when jigging for other fish (C.F.).

[13] **Whitefish:** Harvest estimates seem accurate. They are generally not harvested much. In year 2 a training program run by the school may have resulted in the higher catch that year (C.F.).

[14] **Cod:** Harvest estimates appear low. Several families fish for cod and estimates of about 100 per year would be more realistic (C.F.).

[15] **Mussels:** Most hunters did not know they had to report mussels so much of the harvest was not recorded. Many people harvest mussels and one person can collect over 300 in one day alone. Estimates should be in the 1000's (C.F.).

Appendix I

Article 5, part 4 of the NLCA
PART 4: NUNAVUT WILDLIFE HARVEST STUDY

5.4.1
A Nunavut Wildlife Harvest Study (Study) shall be undertaken in, and cover, each of the three Regions of the Nunavut Settlement Area. Terms of reference for the Study are set out in Schedule 5-5.

5.4.2
The Study shall begin in each of the three Regions on or before the first anniversary of the date of ratification of the Agreement. The Study shall be carried out under the direction of the NWMB.

5.4.3
The research, data collection and fieldwork associated with the Study shall be designed to promote maximum harvester participation and shall be contracted to an appropriate DIO, and supervised by the NWMB.

5.4.4
The Study shall be undertaken over a period of five years, and shall be fully funded by Government. The NWMB shall prepare a budget for the Study which will be subject to review by Government.

5.4.5
The purpose of the Study shall be to furnish data, to establish current harvesting levels, to assist the NWMB in establishing levels of total allowable harvest and, in general, to contribute to the sound management and rational utilization of wildlife resources in the Nunavut Settlement Area. To this end, the Study shall:

(a) document the levels and patterns of Inuit use of wildlife resources for the purpose of determining the basic needs level; and
(b) gather, review and analyse existing biological, ecological and harvest data pertinent to the management of wildlife in the Nunavut Settlement Area.

5.4.6
Raw and interpreted data produced from the Study shall be fully and freely available to the Government of Canada, the Territorial Government and Inuit.

5.4.7
The NWMB shall ensure that the names of individual harvesters are not revealed when making available data pursuant to Section 5.4.6.

5.4.8
Without the prior written permission of the DIO and affected individuals, evidence obtained through the Study relating to an individual shall not be admissible in any proceeding where the individual may be held civilly or criminally liable.

5.4.9
The NWMB shall report annually on the progress of the Study. Upon completion of the Study, the NWMB shall publish a comprehensive summary of the findings of the research.

NOCIR Form

Nunavut Wildlife harvest study

NOTIFICATION OF CHANGE IN REGISTRATION

Field Worker. Fill in sections 1, 2, & 3 as required. Fax a Copy to your Regional Liaison Officer.

Section 1 | **Today's Date** / /

Name of Hunter | **Community**

Type of Hunter **Intensive** ☐ **Active** ☐ **Occasional** ☐

Is this hunter already registered for the Study? **Yes** ☐ **No** ☐

Hunter's current ID number

If you know it

Hunter's new ID number

RLO or Coordinator only to assign a new ID number

Section 2 | **The hunter identified above no longer hunts here because they are:**

Deceased ☐ **Incarcerated** ☐ **Moved** ☐ **Other** ☐

Date **MONTH:** **YEAR:**

Section 3 | **Fill in this section if the Hunter is moving**

Community moving **FROM:** **TO:**

(OFFICE ONLY) Will this hunter also be added to the interview list? YES NO

Nunavut Wildlife Management Board

Draft Report on Inuit Knowledge Regarding Climate Change and the Baffin Bay Polar Bear Population

Martha Dowsley

October 2005

Executive Summary of Draft Report on Inuit Knowledge Regarding Climate Change and the Baffin Bay Polar Bear Population

Martha Dowsley

During spring, 2005, interviews were conducted with elders and senior hunters in the three Nunavut communities which harvest polar bears from the Baffin Bay population (Pond Inlet, Clyde River and Qikiqtarjuaq). Between 15 and 20 interviews were conducted in each community focusing on observations of changes in the polar bear population, observations on the climate during the last 15 to 20 years and also peoples' views of bear management. The results are presented by community, and include quotes from participants explaining their answers.

There are several general trends in the responses regarding the Baffin Bay polar bear population. 83% of respondents said that the population had increased. The reasons for this conclusion were that more bears were seen near the communities and near cabins and camps, and that hunters were encountering bear sign in areas not previously used by bears. Some people noted that these observations could reflect a change in bear behaviour rather than an increase in population. 62% of respondents said that bears are less fearful of humans, and 94% said that bears are causing more damage now than 15 years ago. 57% of respondents reported that bears tend to be skinnier now and 5 people in Clyde River reported an increase in fighting among bears.

Discussions about climate change showed that there is high variability in the environment. There were general trends indicating that the floe edge is closer to the shore now, the sea ice is thinner, there are fewer icebergs and glaciers have receded. People were not sure whether climate change was affecting polar bears or what those effects might be.

Respondents were asked several questions about polar bear management in the Baffin Bay area. People did not know much about polar bear hunting by Greenlanders. They also held varying opinions about the quota system and whether or not it was responsible for the increase in the bear population since the 1960s. When asked about their views on the biologists' studies of bears, there was again a mixed response, with some participants feeling concern for the long-term effects on bear health and quality of meat. Many respondents also did not really understand how the government is set up or how the biological studies were carried out, and also expressed shyness about asking for more information or help from government employees.

Conclusions

The results show there is some change that has resulted in more polar bears being seen around the Baffin Bay communities, and there are changes in bear behaviour and health. The fact that people are seeing more bears has led many people to believe there is an increase in the polar bear population. There are some trends in observations of climate change, but also much yearly variation. This topic should be studied further. Finally, the responses show that wildlife managers need to talk more to the communities about polar bear management and about the specific issues concerning the Baffin Bay population.

Draft Report on Inuit Knowledge Regarding
Climate Change and the Baffin Bay Polar Bear Population

Martha Dowsley

Introduction

This report summarizes the traditional knowledge relating to polar bear populations and climate change observed by Inuit in the three Baffin Bay communities –Pond Inlet, Clyde River and Qikiqtarjuaq, as expressed in interviews during spring of 2005. Participants were asked questions regarding polar bear population, behaviour and health (Section 1), climate change (Section 2) and understandings and views on the management of polar bears in Baffin Bay (Section 3).

Methodology

The interviews were conducted from April to June 2005 in the three Baffin Bay communities. Most interviews were conducted in the homes of the respondents (senior hunters and community elders), and generally included a translator. Interviews lasted between one hour to one and a half hours.

These questions were part of a larger interview related to my PhD thesis and the interviews were purposefully relaxed so that respondents could expand on topics that they knew a lot about or were more comfortable discussing. For this reason the number of respondents to each question varies. People were also generally unprompted with regards to possible explanations of their observations. This was done to allow them to express their own views and not be influenced by what I might want to hear.

Section 1 Observations on polar bear population and behaviour

Q 1 Has the polar bear population increased, decreased or stayed the same over the past 10 to 15 years?

Pond Inlet

All 15 respondents indicated that the bear population has increased. 13 people offered explanations. Seven said there were more bears around the community or cabins. Seven said there were more bears and bear signs on the land. One person said the bears were forced onto the land because there is less ice.

Some comments:

"There are too many polar bears now, most of them will be hungry and prone to attack people. Before there were never polar bears around here until recently."

"There were not many bears around Pond Inlet when I was growing up. We used to have caches of muktuk and seal. The polar bears only bothered them once in a while. Now there are lots of polar bears! I never suspected there would be polar bears in the western fiords and now there are. There are fewer seals there, but the bears are probably looking for food over there."

Clyde River

16 people answered this question. 14 said the population had increased. One said the increase was only slight and the other said there was no change. Nine of the people who said the population has increased gave reasons. 5 said there were more bears nearby, that people didn't have to go very far to hunt them anymore. 2 people said they were seeing lots of young bears and bears with no ear tags. Two other hunters gave different statements:

"When I was young at the Home Bay area, there was a lack of polar bears. But in April and May the big males come looking for females there now."

"There are too many bears. Before, when we went dog teaming for hunting we didn't come across many bears. We were getting 45 a year anyway. The government says that's too many. We should be able to get more now since we were able to get that when they were scarce."

Qikiqtarjuaq
16 people answered this question. Four people said they didn't know if the population had changed. Nine people said the population had increased and 3 said the population was the same.

Ten people explained their answers further. For the people who said the population had increased, 4 said they knew the population had increased because they were seeing bears near the community. One person said he had seen more signs out on the land. Two people said they had seen bears or signs where there didn't used to be any bears.

Three of the people that weren't sure offered these observations:
"I don't know. The polar bears are usually at the floe edge and the sea. But this year they are not really down at the sea. They are more by the land. Probably there is not enough to harvest there (not enough food at floe edge). And there are walruses by the floe edge so the seals are probably more close to land."

"I can't answer, but I think they increased, but it could be due to change of weather or the polar bears are following their prey. We say they have increased because the weather got warmer and probably the polar bears have come nearby the communities. They are coming more to the community."

"I tend to believe the biologists. They are saying there are fewer bears. So I'm sticking with them. Even though I've seen a lot of bears and they look like they're increasing."

Q 2 In open water season have you seen changes in polar bear behaviour such as when they come to shore or what they do once they are on shore?

Pond Inlet
7 people responded to this question. All indicated there was no change in when bears come to shore. 5 respondents stated during their interviews that bears had lost their fear of people. One elder explained this:

"Long ago polar bears would go away fast. When there are more animals of any kind they are less afraid. We used to have lots of caribou around town, even right here, beside the house. It was the same thing. When there are fewer animals, when the hunter is trying to catch them he has to be really quiet. But when there were lots of caribou, one was sleeping in front of the house. He didn't get up or care about the noise."

Clyde River
15 people answered this question at least in part. Three people said there was no change in behaviour of the bears when they come on shore. Five people said the bears are not scared of people anymore. One person noted that hungry bears do not scare easily, whereas well-fed bears do. The other respondents said there was no change in when the bears come on shore, though one person offered a more detailed answer:

"Usually they come after the break up season. They come to the fiords, some stay out swimming and come on land to sleep, some are more curious than others. They usually come after the land fast ice breaks up, when the multi-year ice washes in from the north. When you scare them away (from town) they get used to it and they learn you won't hurt them."

Qikiqtarjuaq
5 people answered this question. One said more bears are coming. One said he didn't know. The others indicated no change had occurred in timing or behaviour.

Q 3 Are there more or fewer bears around town now than 10-15 years ago?
Pond Inlet
7 people responded to this question. Six said more bears were coming. 1 person said the number varies. Even though many people used the presence of bears in town during the fall as an indication that their population had increased, some respondents gave more textured answers:

"It seems to be that more are coming to the community. When the polar bears are hunting they are not so careful because of the noises they always hear. Even dogs' barking damages their ears. So polar bears are not as successful at hunting so they come to the community to find food." (see health question, #6, for more details on this explanation).

"They started coming to town in the 1960s, early 1970s. Polar bears can think like a person, they won't forget things right away. If they come and find food around here, people chase them away and the polar bear will come again the next year. They will remember where they found food. If a bear is chased away from town, it will come back at night when things have quieted down."

"Polar bears don't like the smell of dogs and they used to stay away because we had dogs everywhere. Now there are fewer dogs so the bears come to the settlements. We used to cache meat and they didn't bother it. Now there are more bears and they dig up the caches."

Clyde River
14 people answered this question and all agreed that more bears were coming to town in the fall.

"More are coming to town, because there are more bears, not because they are extra attracted to town. It's a different bear almost every time, but skinny ones keep coming back."

"In the fall they seem to be hungry, they've been lying around for a long time. The town bears are also more likely to be young ones."

Qikiqtarjuaq
13 people responded to this question. Five said more bears come to the community in the fall. Two said more come to the island in general but not necessarily the community and 6 people said it is the same as at least 10 years ago.

"Back then we only saw them (around the community) when there was no ice. Now even in the winter they come around."

Q 4 Compared to 15-20 years ago, are there more, fewer or the same number of tracks, bear kills and bears seen when you go hunting in spring, summer, fall, winter?
Pond Inlet
9 people responded to this question. Four said there were more bears in all seasons, no one said there were more just in winter, four said there were more in spring, one said summer, and one said fall.

"Before we had a certain time to see polar bears –during March and April when the polar bears are looking for seal pups and during the full moon. Now any time we can see them."

"Since 1990, even when you go out boating you can see more, for example sleeping on the shore."

Clyde River
14 people responded. One person said it was the same as 15 years ago. Seven people said you could see more bear signs in all seasons. Three specified spring as having more bears and 4 specified fall as a time to see more bears than previously.

Qikiqtarjuaq
11 people responded to this question. Four said there were more bears in general. Two said there were fewer in the winter, while one person said there were more in winter. Three people said there are more in spring and one person said there are more in summer.

"They rotate. Some years they are in different places. In the last four years they have been further south, before that they were further north. 15 years ago in some places you could see more. A few weeks ago we saw more tracks to the north."

A sport hunt guide said that they couldn't find bears to the south of the community in spring 2005 and one of his clients was unsuccessful. He took the next client north and saw many bears.

Q 5 Is there more less or the same damage to cabins, meat caches and other equipment? If there is more damage, why is that?

Pond Inlet

The 11 respondents all agreed that bears cause more damage now than ten years ago. 5 people said it was nearly impossible to have a meat cache now. One person explained that people are building cabins out on the land more than before because tents are too vulnerable to bears. One respondent said that in the early 1960s it was also impossible to have a cache.

"They don't run away when they hear something. They don't care. They are causing more damage too, they even go up to tents and bother people."

Six respondents elaborated on their observations about more damage. Two respondents said that it was because the bear population was too high. Four people stated that the noises caused by machines, dogs and the act of conducting research on bears causes the bears to lose their hearing. The bears then cannot hunt as well and are not as afraid of humans. This results in bears coming around people more.

Clyde

14 people answered this question. 13 people replied that bears are causing more damage now, in particular to cabins and meat caches. One respondent didn't know if there was more now or not.

"There seems to be more damage, but you have to take into consideration that we're leaving more stuff out on the land than 15 years ago. But if you leave meat caches they are pretty much guaranteed to be gone."

"We used to cache 4 or 5 seals in a row, covered them just with gravel. Used to never be touched. But now it disappears even if we put rocks on it. Polar bears don't like to use their claws and scratch them (wear them down), so they stayed away from the gravel. They wouldn't dig it. Now they do."

A total of nine people explained why they thought there was more damage. Three people only explained it was because there are more bears now. Two people said it was because there are more bears and more fighting and some can't get food, so those bears come to where people are. Two respondents said the bears got used to people and the same ones kept coming back. Two respondents said there are more people and more food around, which was attracting bears.

Qikiqtarjuaq
Six people responded to this question. Five of them said there was more damage and one person said it was the same. All the people who said there was more damage elaborated on why. Three said it was because there are more human things around for bears to get into. One person said it was because there are more bears. One blamed the environment: "The bears are more hungry. There is a problem with the ice. The rough ice makes it hard for them to find seals, but there is the same number of seals."

Two people also mentioned a lack of fear:
"The only change I've noticed is when I was growing up the polar bears would scare easily and run away. Even when they were around shacks they didn't break windows or do damage but now they are not afraid. They used to avoid communities before and now they don't."

"More people are hunting them. In the past, using harpoons, only experienced hunters would go for bears, now with rifles, anyone can hunt, even women, so the bears are less afraid."

Q 6 What is the health of the bears that come to town?
Pond Inlet
Ten people discussed this question. Two people said there is no pattern. Eight said the bears that come to town are skinny.

Clyde River
For town bears there were three responses, one said skinny bears come to town, while another person said any kind come to town but skinny ones keep coming back. One person said there was nothing different in the health of town bears compared to other bears.

Qikiqtarjuaq
Only one person commented specifically on town bears. He said that the ones that are close to the community are fatter than ones further away.

Comments on the general health of bears
Pond Inlet
There were 7 comments about the general health of bears. 4 said it was variable
2 said there were more skinny bears in general now. The seventh respondent stated:
" I noticed since they started tagging bears, the ones with the tags were the skinniest. Even now when we look for bears, we go further to where they aren't so skinny and the meat is better."

Three elders talked about a loss of hearing in polar bears. One indicated that the bears no longer care about noises around people, one said that when an animal's population is high the animals lose their fear and don't mind loud sounds. Both of these could indicate that

bears are getting used to noises, however, the third respondent was adamant that the reason was hearing loss:

A: "There are many more polar bears and I know exactly why. Right now their hearing is worse because of helicopters and airplanes that did research on them, gunshot sounds, these things make them deaf. That's why they can get close to town."
Q: What about their sense of smell?
A: "They got used to our smell....For the proof that polar bears are losing their hearing due to how research is done, their hearing is worse from the tranquilizer. Back then the polar bears could hear dogs coming from far away and if the polar bear got away his ears were already damaged."

Clyde River
14 respondents discussed general bear health. Seven respondents said polar bears are skinnier over all, while one respondent said only males were skinnier now. Five people said there was more fighting among bears as evidenced by more scars, broken canines and the discovery of bears that had died from fighting. One person said cubs are leaving the dens earlier and one person mentioned that cubs leave their mothers earlier due to big males attacking them. Four people said there was no change in overall bear health.

One person mentioned hearing loss:
"Skidoos hurt their ears. IQ says when we used to hunt with dogs, if you missed a bear it would have damaged his hearing and he will be less lucky in hunting and get skinny. So hunters say 'it's too bad we missed that bear' not because they wanted to get it, but because they know that afterwards the bear will be damaged."

Qikiqtarjuaq
Six people commented on general bear health. Two people said it was variable. Three said there are more skinny bears. Two gave other comments:

"Now people are finding more dead bears that climbed the mountains and fell down – they were looking for eggs."

"The wolves are actually injuring and hunting the cubs and now the wolves are a problem by killing the cubs. We never used to see wolves so we were not aware of any killing of cubs. But for the past 3 or 4 years the number of wolves has increased. From IQ we know the caribou are coming, the wolves move before them, so probably the caribou are coming. A hunter has seen a cub that was killed by a wolf pack."

Section 2 Climate Change Questions

The issue of climate change is very complicated, especially since there is high yearly variability in environmental conditions. Certain aspects of the environment certainly seem to be different in all three communities, but interviewees gave varying answers to the questions. The low number of responses may indicate that although the respondents thought about that aspect of the environment they had not noticed changes and therefore did not say anything because they were specifically asked about changes.

Q 7 Have there been any changes in the ice? Floe edge, icebergs, rough ice, changes in amount of snow?

Pond Inlet

14 people replied to this question, 13 said there had been changes while the other person replied that there had not been. People were asked to expand on the sorts of changes they had seen in the past 10 to 15 years and were sometimes prompted with examples of the sorts of changes I was interested in.

Quality of Ice

Eight people said that the general quality of the sea ice has changed. Four mentioned that the ice is thinner now. One said the land fast ice is often more slushy, another said there is less multi-year ice and there is less ice in spring. Comments about the hunting area around Button point included that the ice there is thinner now, that there is no ice there now, and that it is more smooth ice and one can drive a skidoo there in winter now whereas one could not in the past.

Cracks in Sea Ice

One said there were fewer cracks now because the ice is thin and one said that nothing about cracks had changed.

Break up

Four people mentioned break up as being faster during July and that it begins up to two weeks earlier, while one person said the time of break up had not changed.

Freeze up

Three people mentioned that freeze up is later. In the past it was in October but now it takes place in November or December. During this time the ice is more brittle.

Icebergs

Ten people mentioned icebergs, nine of them said there were fewer icebergs now, while one said the number varies.

Floe Edge

Seven people mentioned the floe edge. Of these, 6 said it was closer now and the other respondent said that it was a bit different. Two of the people who stated that the floe edge was closer gave the following explanations:

"The icebergs are like nails, they hold the ice in. Since there are fewer icebergs there (around Button Point) the ice edge is closer."

"When I'm flying to and from Clyde River, there are not a lot of icebergs and the floe edge is closer to the land. In the Clyde River area, way back, when there were lots of icebergs, the floe edge was further out. Recently there are strong winds from the south so the icebergs left and the floe edge came in closer. The icebergs come from Greenland (between Greenland and Ellesmere) and they go into Clyde and the coast just north of it. The current is from the north and from Lancaster Sound coming east... The ice changes in Baffin Bay mean less ice patches so the bears come to land to hunt. Because polar bears can swim, but when they are tired they go to land. Probably Clyde people know more because when there is no ice on the ocean, the polar bears go to land, mostly by Clyde River."

Glaciers
4 respondents mentioned that the glaciers are receding.

Snow
Two people said there was more snow and one said there was less snow on the land.

Clyde River
16 respondents answered this question. Three said there had been no significant changes. The others expanded on their observations about specific features.

Ice quality
6 people mentioned that the ice is thinner now. One person explained that there is more snow on the ice and this insulates the ice and stops it from being so thick. Two people said ice quality was variable and there was no pattern of change.

"The ice is sharper now, not as hard as before. In the past the ice was really thick. The cracks were very narrow, deep and tapered down like a 'V'. Now they have straight edges."

"The salt water doesn't freeze as hard as before. Every year we chip the ice at seal breathing holes, today it is not as hard, not as brittle. Now in June the bottom of puddles (on the ice) is not slippery, it's not melting from the top, it's melting from everywhere through the ice, like the inside of a bone. Today the ice is also thinner. People used to say when the leads opened they looked tapered going down in them because of the thickness. They no longer look tapered."

Cracks in Sea Ice
Three people said there was no obvious trend regarding cracks. Two people said there were more cracks and one person said sometimes there are hardly any cracks.

Ice Bergs

There were 12 responses about icebergs. 10 people reported that there are fewer icebergs. Two people reported no change in the number of icebergs.

Floe Edge
Four people said the floe edge was closer now and one person claimed it was different now, but did not elaborate.

Rough Ice
Eight people discussed rough ice. Three said there was no change. Four people said there was more rough ice. Two of these people explained the rough ice is caused by there being fewer icebergs to hold in the ice. One person said the rough ice occurs when the wind is from the south or east.

Break up
Six people gave responses about spring break up. One said it is about the same as in the past. Five said it was earlier now. One person specified a change of about 2 weeks earlier.

Freeze up
Four people said it was a couple of weeks later now. One person said it is highly variable.

Glaciers
Two people mentioned glaciers and said that they are melting more around Clyde River.

Wind
Four people mentioned wind. One said it is variable, and one said there was less wind. The other two gave these comments:
"We used to only have wind from the north. 3 or 4 years ago the wind started coming from the south too."

"Seems like there is more wind. Seems to be more strong winds. It was soft snow in the south, less blowing snow. Now the snow is harder there (from being blown more)."

Qikiqtarjuaq
13 people responded to this question. One of these people said there was no change because everything is highly variable. The others gave details about specific changes.

Ice quality
Four people said the ice is thinner now and getting more dangerous. One also said there is less pack ice.

"I went bear hunting all the way to the Dewline on Durban Island and the ice there was moving up and down. That was 4 years ago in March. It was not like that there when I was growing up. It was solid."

Cracks
One person said cracks appear earlier in the spring and there are more of them. Another person said there are usually leads open in winter off the north end of the island but lately there haven't been.

Icebergs
8 people commented that there are fewer icebergs now.

Floe Edge
Six people all answered that the edge is closer to land now.

"The floe edge is closer to the land and there are hardly any icebergs. That's why the floe edge is close by. The icebergs keep the ice from going anywhere. They are like plugs."

Rough Ice
Two people mentioned there is more rough ice. One qualified that by explaining that the floe edge is closer and the rough ice is generally by that, so the rough ice is close to the land now.

Break up
Three people said break up is earlier now.

Freeze up
One person said freeze up is later and slower now.

Snow
Two people mentioned snow, one saying there is more and one saying there is less.

Glaciers
Three people discussed a snowcap that used to stay all year on a mountain on Qikiqtarjuaq Island. There used to be bear dens in this snow, but now the snow doesn't stay all year and the bears no longer den there.

Q 8 Have you heard of global climate change? Have you seen any evidence of it in your area?

Pond Inlet
Six people responded to this question. 5 said they believe the changes they have observed are caused by this. The other respondent said he did not think he had observed any changes that could be attributed to climate change.

Clyde River
15 people responded to this question. 9 people said it was getting warmer, while 6 people said the climate fluctuates a lot so there is no evidence of a warming trend.

Qikiqtarjuaq
10 people answered this question. Six said it was warmer now and one said there is more variation now. Two people made specific comments on changes:
"Yes, it has affected our area. In the past we could hunt for different animals further. Now we can't go further, we have to hunt nearby on the ice." This comment seemed to refer to the difficulty of traveling on the ice.

"I am experiencing it. In winter there are usually cracks from the points of land and I can put my net under water. But now there are hardly any cracks so I can't fish for char any more."

One said there was no change
"I don't know anything about the environment. I don't think there is any global change. It is now May and there should be spots where it should have melted but there aren't and it is still frozen. So it doesn't appear to be warmer."

Q 9 Could climate change contribute to what you have observed about polar bears?
Pond Inlet
Three people responded to this question, all said they didn't know.

Clyde River
Three people gave responses:
"No, because polar bears can go and follow the seals further, so they won't have trouble hunting. Also the snow covers the breathing holes but polar bears can still hunt, it's just for people."

"Seems like yes because polar bears are getting skinnier. If it gets warmer it will affect polar bears. They like to be cold."

"Yes, it could effect the polar bear's food, even with small amount of temperature change, the food will change. These days some livers (of seals) don't look good. Also the shedding of the seal fur. Molting is this time of year usually. Now you sometimes find ones that are molting in other times of the year."

Qikiqtarjuaq
Five people responded. Two said 'I don't know'. The other three gave comments:
"It may be. There are not enough icebergs and the denning areas have less snow and it is melting in summer. The bears are more hungry. There is a problem with the ice. The rough ice makes it hard for them to find seals, but there are the same number of seals."

"Harp seals usually have breathing holes during the winter but because the weather is always changing, the ice freezes over quickly and so the seals are on the surface of the ice. They move around on the top of the ice, they can't get back in their holes because the holes froze. Then they are killed by polar bears."

"Maybe the ice in the sea is melting and the bear have no where to go. It is very noticeable, they will go to land. There are no icebergs for them to go to."

Section 3 Understandings of Management

Q 10 What do you know about polar bear hunting by Greenlanders?

Pond Inlet

Four people discussed this question, three did not know much about it, but one commented:

"I've heard they are catching more. Sometimes polar bears go from here to Greenland and they don't have a quota system so it will affect our quota. They use polar bear skins for clothes so they are hunters too."

Clyde River

There were 5 responses to this question. Two said they didn't know anything. One said he heard they catch more polar bears there, while another only knew they use dog teams for hunting bears. The fifth person said:

"There is more hunting there because it's a part of their lives. More hunting there than here, it's like it was here 30 or 40 years ago."

Qikiqtarjuaq

Three people answered this question. Two said they didn't know much about it. The other said on television it shows they have polar bear clothes.

Q 11 Can you tell me about the quota system here? Do you agree with it?

Pond Inlet

10 people discussed the quota system. Five said they like the system while two specifically said they like the increase in the number of tags. Three people said they don't like the specific rules and two people want more tags. Most people gave comments:

"A few years ago I though the quotas were not useful, but then they increased the number of tags so I'm okay with it now. We wouldn't even need quotas now because people see bears and don't even try to get them. If we stopped using quotas we could probably manage. The fur value is decreasing so people don't even try to catch them. Soon the only money from them will be from sport hunt guiding."

"We can't have all the bears that there are. So it has increased the population of bears, it's like that all around. Before people would get all the bears. The population will decrease since we can only catch males, so soon the population of males will be so little."

"I like the idea of the quota. If we don't have a quota and there are more hunters we'll have fewer polar bears. The population will go down."

"I don't like the idea of the quota system. It's only in winter and none in summer and we should be able to get bears in summer. They are dangerous when they are hungry."

Clyde River
11 people discussed the quota system. Seven said they like the quota going back to 45. Two said they wanted it higher. One said he liked the system in general and didn't care if the quota was high or low. One person wanted the quota to allow the taking of any bear because males have tough meat.

"I like it at 45. I'd be concerned if the polar bear quota dropped and we still had problems and also if we couldn't fill the quota, that would be a major concern. But lots of bears come into town and there were a lot around this spring."

Qikiqtarjuaq
Three people responded to this question. These are their comments:
"A sad part is that elders used to eat cubs but they are not able to do that now and they miss that. The quota system is not very efficient. If I had to shoot one (in defense) it is taken away from the quota. There are too many bears now."

"It's much better (to have quota system). If we don't have it more bears get shot."

"I'm happy they increased the quotas because there will be fewer bears in the community. Recently at A's outpost camp there were three bears."

Q 12 Were there more or fewer bears before the quota system began?
Pond Inlet
Seven people responded to this question, all agreed that the quota system was at least partially responsible for the increase in the bear population.

"The population has increased since we got quotas, because we can only kill so many. They shouldn't have the quotas because the polar bears are dangerous. We should be able to get them year round."

Clyde River
4 people discussed this question. Two people said the bear population was the same before the quota and now. One said there were more bears but didn't know if the quota had caused this. The final respondent said this:

"We caught fewer bears before there was a quota. Now there are more bears. The quota allows more bears to be caught."

Qikiqtarjuaq
Only one person responded to this question: "Before there was no law about hunting season, now there is a law, that's why there are so many now."

Q 13 What do you think about biologists catching bears?
Pond Inlet
Seven people responded to this question. Two people said research hurts the bears' hearing and makes them skinny. One person said he like biologists and liked working

with Mitch Taylor. One person suggested studying them all year and another said he is now supportive of the research because the population did not move away. Some people were concerned about how research affects bears:

"The temper of the bears change and they become more dangerous."

"Sometimes we don't want to eat animals that have been researched. So when we get a polar bear with an ear tag, they way 'that's a government bear' and it's usually skinny. We really don't want to eat those ones that are tranquilized. We feel it isn't safe. Maybe it is, but that's what we feel. When we see polar bears being put to sleep and measured, we see them as being abused by those people."

Clyde River
Three people answered this question. Two people said they don't believe the biologists and that the population has increased. They suggested biologists should study the population all year round. A third person said that research hurts the bears' ears and makes them skinny.

Qikiqtarjuaq
Two people gave information about biologists:

"The NWMB appoints them to do research on bears."

"I don't go to meetings but we always hear about it. We hear that polar bear and caribou are decreasing and they tell us how many there are."
Q: Did the biologist tell you why the polar bears are decreasing?
"Because maybe they are being controlled and it is similar to retaliation."

Other Comments
During the interviews some people who were particularly knowledgeable were asked questions related to this study but not part of the questionnaire.

Pond Inlet
Q: the Government thinks there are fewer bears, but hunters are seeing more, what should be done?
A: " We're not really worried about that. It's like this, in Alaska there is no quota for bowheads, but we are getting more bowheads. So maybe what others do doesn't impact us.

Q: the Government thinks there are fewer bears, but hunters are seeing more, what should be done?
A: It's the same as if someone told me the cows are less numerous down south, I might say to stop killing them. I lived here my whole life and so I believe what I see, not the researchers.

Qikiqtarjuaq

Q: Some people think the sea ice is melting and that is why the polar bears are coming to land more. Could that be true?
A: I believe that is actually happening because the snow banks have melted and the ice tends to melt more quickly and when there are no icebergs they need to get dry on land so they have to come to land.

Q: Do you think the population could actually be decreasing because of climate change?
A: I sort of believe that too, knowing the dens have melted. The ice on the mountains on Qikiqtarjuaq melted starting in 1968 gradually, but that is an estimate.

General Comments About the Government

Several interviewees complained that government employees do not listen to their problems. I think most relate to a lack of communication between government representatives and local people. Here are the concerns expressed to me:

"Government should listen to Inuit, we should be able to hunt in summer. The quota should be open all year."

"Last summer someone caught a harp seal with a square head from sickness. Inuit don't want to eat sick or skinny seals. What should I do about these things?"
Me: Take a sample and give it to the wildlife officer.
"We tried to go to the officer but we are always told to just throw it away because they don't believe there is sickness or skinniness."

"I was camping with my brother and I killed a bear that was wrecking my tent near Tasialuit, south of Canso Channel, last summer. The wildlife officer wanted to come and take a picture but he never came. Why? Doesn't he care?
Me: Tell him again. Maybe he doesn't have money to give to you.
"I won't go to him again. He won't help if he didn't help the first time.

Conclusions

Population

People generally think the bear population has increased, because they have seen more bears near human habitation and also bears have been appearing in places that did not used to have bears.

Behaviour

Many respondents said that bear behaviour has changed to be more tolerant of people. In Clyde River people noticed more fighting among bears.

Health

People often reported that bears are skinnier now than in the past. No one mentioned any difference in the number of cubs seen per female bear, although this was specifically queried during the health section. Some elders are concerned about hearing loss in bears caused by noises from machines, dogs and research activities.

Climate Change and Possible Impacts on bears

Climate change observations varied widely among participants. There is a general consensus that there are fewer icebergs now than in the past, and as a result the floe edge is closer to the land. Respondents did not have a clear idea of how, or if, this was affecting bears.

In Qikiqtarjuaq the disappearance of year-round snow in denning areas on the island was mentioned often and given both as evidence of climate change and as evidence to how it might affect bears.

Management

Respondents generally expressed that the problem was that too many bears were seen around people and that it was dangerous.

Many people were ignorant of the management system or the reasons for it. They also expressed reluctance to seek better information from either their HTOs or the government. This behaviour may be cultural and should be addressed by wildlife managers.

Appendix 1 Interview Questions

Q 1 Has the polar bear population increased, decreased or stayed the same over the past 10 to 15 years?

Q 2 In open water season have you seen changes in polar bear behaviour such as when they come to shore or what they do once they are on shore?

Q 3 Are there more or fewer bears around town now than 10-15 years ago?

Q 4 Compated to 15-20 years ago are there more, fewer or the same number of tracks, bear kills and bears seen when you go hunting in spring, summer, fall, winter?

Q 5 Is there more less or the same damage to cabins, meat caches and other equipment? If there is more, why do you think that is happening?

Q 6 What is the health of the bears that come to town?

Q 7 Have there been any changes in the ice? Floe edge, icebergs, rough ice, changes in amount of snow?

Q 8 Have you heard of global climate change? Have you seen any evidence of it in your area?

Q 9 Could climate change contribute to what you have observed about polar bears?

Q 10 what do you know about pb hunting by Greenlanders?

Q 11 Can you tell me about the quota system here? Do you agree with it?

Q 12 What do you think about biologists catching bears?

Q 13 Were there more or fewer bears before the quota system began?

SOI	Shell Offshore, Inc.
SPL	Sound Pressure Level; the SPL for a seismic pulse is equivalent to its rms level
SZ	Shut Down of all airguns because of a marine mammal sighting near or within the safety radius
TTS	Temporary Threshold Shift
UNEP	United Nations Environmental Programme
"Useable"	Visual effort or sightings made under the following observation conditions: daylight periods within the Chukchi and Beaufort Seas, ***excluding*** periods 3 min to 1 h (pinnipeds) or 2 h (for cetaceans) after airguns were turned off (post-seismic), periods when ship speed was <3.7 km/h (2 kt), and periods with seriously impaired sightability. The following conditions were defined as involving seriously impaired sightability: all nighttime periods, and daytime periods with one or more of the following: visibility <3.5 km, Bf >5 (Bf >2 for porpoises), or >60º of severe glare between 90º left and 90º right of the bow. Sightings of marine mammals hauled out on the ice in both the Beaufort and Chukchi seas were considered "useable" for analyses. Sightings of cetaceans from the *Kilabuk* were considered "unuseable" for analyses.

EXECUTIVE SUMMARY

Background and Introduction (Chapter 1)

Shell Offshore, Inc. (SOI), collected marine seismic data in the Chukchi and Beaufort Seas during the summer of 2006 in support of potential future oil and gas leasing and development. Deep seismic acquisition for SOI was conducted in the Chukchi Sea by WesternGeco using the M/V *Gilavar*, a source vessel that towed an airgun array as well as hydrophone streamers to record reflected seismic data. Seismic acquisition was originally planned to be conducted in both the Chukchi and Beaufort Seas using the *Gilavar*; however, ice conditions during the 2006 field season precluded most data collection in the Beaufort Sea. Activities in the Beaufort Sea were confined to site clearance, shallow hazard surveys and geotechnical activities, which were conducted from the M/V *Henry Christoffersen*, an NTCL vessel.

Marine seismic surveys emit strong sounds into the water that could affect marine mammal behavior and distribution, or perhaps cause temporary or permanent reduction in hearing sensitivity. These effects could constitute "taking" under the provisions of the U.S. Marine Mammal Protection Act (MMPA) and the U.S. Endangered Species Act (ESA). The National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS) share jurisdiction over the marine mammal species that were likely to be encountered during the project. Cetaceans and most pinnipeds are managed by NMFS; Pacific walruses and polar bears are managed by USFWS.

SOI's seismic surveys and other exploration activities in the Chukchi and Beaufort seas were conducted under the jurisdiction of Incidental Harassment Authorizations (IHAs) issued by NMFS and USFWS. The IHAs included provisions to minimize the possibility that marine mammals close to the seismic source might be exposed to levels of sound high enough to cause hearing damage or other injuries, and to reduce behavioral disturbances that might be considered as "take by harassment" under the MMPA. Under current NMFS guidelines, "safety radii" for marine mammals around airgun arrays are customarily defined as the distances within which the received pulse levels are ≥180 dB re 1 μPa (rms) for cetaceans and ≥190 dB re 1 μPa (rms) for pinnipeds. Those safety radii are based on an assumption that seismic pulses at lower received levels will not injure these mammals or impair their hearing abilities, but that higher received levels *might* have some such effects. The IHA issued by NMFS required monitoring of the distances within which received sound levels would be ≥180 and ≥190 dB, and implementation of appropriate mitigation when marine mammals were seen within or about to enter those zones. The IHA also required monitoring of the distance within which received sound levels might be ≥160 dB re 1 μPa (rms).

NMFS and USFWS granted the IHAs to SOI on the assumptions that

- the numbers of whales and seals potentially harassed (as defined by NMFS criteria) during seismic operations would be "small",
- the effects of such harassment on marine mammal populations would be negligible,
- no marine mammals would be seriously injured or killed,
- there would be no unmitigated adverse effects on the availability of marine mammals for subsistence hunting in Alaska, and
- the agreed upon monitoring and mitigation measures would be implemented.

The main purpose of the mitigation program was to avoid or minimize potential effects of SOI's seismic survey on marine mammals. This required that shipboard personnel detect marine mammals

within or about to enter the designated safety radii, and in such cases initiate an immediate power down (or shut down if necessary) of the airguns.

Mitigation was also required at the 160 dB isopleth. This area was monitored by the chase boat that accompanied the seismic vessel. Power down of the seismic airgun array was required if an aggregation of 12 or more non-migratory bowhead or gray whales was detected ahead of, or perpendicular to, the seismic vessel track. Monitoring of the 120 dB isopleth around the seismic vessel was also required after 25 September in the Chukchi Sea and after 1 September in the Beaufort Sea. Power down was required if 4 migratory cow/calf pairs were detected within the surveyed 120 dB isopleth.

The primary objectives of the monitoring program were as follows:

1. provide real-time sighting data needed to implement the mitigation requirements;
2. estimate the numbers of marine mammals potentially exposed to strong seismic pulses; and
3. determine the reactions (if any) of marine mammals potentially exposed to seismic sound impulses.

This 90-day report describes the methods and results for the monitoring work specifically required to meet the above primary objectives.

Seismic Surveys Described (Chapter 2)

The *Gilavar* was used as the seismic source vessel during SOI's activities in the Chukchi Sea in 2006. The *Gilavar* was accompanied by the *Jim Kilabuk*, an icebreaker-class support vessel (chase vessel). The proposed deep seismic survey was originally scheduled to occur in two phases. Phase one commenced in July in the Chukchi Sea and was planned to continue there until late summer when the *Gilavar* and *Kilabuk* were to transit to the Beaufort Sea to conduct phase two seismic surveys on Shell lease-holdings in the mid- and eastern parts of the Alaskan Beaufort Sea. Heavy ice conditions delayed the date when operations could have transferred to the Beaufort Sea, and seismic operations continued in the Chukchi Sea. During September, SOI decided not to attempt to conduct deep seismic exploration in the Beaufort Sea during 2006 due to high concentrations of ice and other operational considerations. The *Gilavar*'s airguns and streamers were retrieved on 19 September and the *Gilavar* departed southward from the project area and left the Chukchi Sea on 23 September. The geographic region where the deep seismic survey occurred was located in the Chukchi Sea MMS OCS Program Area designated as Chukchi Sea Sale 193 (1989) and in the proposed 2002–2007 Chukchi Sea Program Area.

SOI used WesternGeco's 3147 in^3 3-string array of Bolt airguns for its 3–D seismic survey operations in the Chukchi Sea. For each airgun shot, WesternGeco's source array was composed of 3 identically-tuned Bolt airgun sub-arrays, each with 8 airguns and a total volume of 1049 in^3, operated at an air pressure of 2000 psi. This energy source was towed approximately 245 m behind the *Gilavar*. The system also included 6 hydrophone streamers 4200 m in length and spaced 100 m apart, which recorded reflected sound energy. Air compressors aboard the *Gilavar* were the source of high pressure air used to operate the airgun arrays. Seismic pulses were emitted at intervals of 25 m (~10 sec) while the *Gilavar* traveled at a speed of 4.5 to 5 knots (8.3–9.3 km/h).

SOI used the *Henry Christoffersen* to conduct site clearance and shallow hazards surveys of potential exploratory drilling locations within SOI's lease areas in the Beaufort Sea. The surveys were conducted between 8 Aug. and 2 Oct. 2006, on an intermittent basis as allowed by ice and weather conditions at specific nearshore areas ranging from east of Kaktovik west to Thetis Island near the Colville River Delta.

Offshore site clearance surveys use various geophysical methods and tools to acquire graphic records of seafloor and sub-seafloor geologic conditions. Small geophysical survey sources with limited energy output were employed to measure bathymetry, topography, geohazards, and other seabed characteristics. The strongest sound source was a cluster of four 70 in^3 airguns, which was used on 8 Aug. during the sound source measurements. Two 70 in^3 airguns were used during a deeper site clearance survey on 25 Sept. Those were the only dates in 2006 when SOI operated airguns in the Beaufort Sea. Other equipment used during the shallow hazards surveys included a bubble pulser operating at frequencies near 400 Hz for medium penetration and a chirp sonar operating at 2–7 and 8–23 Hz for shallow penetration. Other acoustic sources used to map the seafloor included multibeam bathymetric sonar operating at 240 kHz and side-scan sonar operating at 190–210 kHz.

SOI originally intended to conduct aerial surveys in the Beaufort Sea in support of deep seismic acquisition by the *Gilavar*. Since SOI did not conduct any deep seismic acquisition from the *Gilavar* in the Beaufort Sea in 2006, aerial surveys in the Beaufort Sea were only in support of the shallow hazards and site clearance activities conducted from the *Henry Christoffersen*.

A series of 8 north-south transect lines was established to monitor the project area in Camden Bay where SOI planned to conduct shallow hazard and site clearance surveys. Nine aerial surveys of the project area were conducted using a Twin Otter aircraft flown at 1000 ft above ground level at airspeed of approximately 120 knots. The first 7 surveys, conducted from 26 Aug. to 14 Sept., were pre-seismic surveys intended to collect baseline data on the distribution and abundance of marine mammals in the project area. On 23 and 24 Sept., surveys were flown to monitor the 120 dB zone around the *Henry Christoffersen* prior to seismic activities on 25 Sept.

Acoustic Modeling (Chapter 3).

Prior to conducting seismic and shallow hazards survey activities, SOI contracted with JASCO Research Ltd. to provide an acoustic model to estimate the extent of ensonification from the seismic acquisition and shallow hazards survey equipment in the Chukchi and Beaufort seas. The purpose of the modeling was to provide estimates of the received sound levels as a function of distance and aspect around the various acoustic sources when operating in the planned study regions. The model applied by JASCO takes account of the specific configuration of the airgun array. It also allows for the effects of the anticipated environmental conditions, including water properties, bathymetry, and bottom conditions, on the propagation of the sound through the water and bottom.

The main sound sources that were considered in this modeling study included three configurations of airgun arrays planned for use during seismic acquisition on the *Gilavar*. These consisted of one, two and three strings of airguns with 8 airguns per string and total volumes of 1049 in^3, 2098 in^3 and 3147 in^3 respectively. Also considered in the modeling were three potential shallow hazards survey sound sources. These were individual airguns of 10 in^3 and 20 in^3 volume, and a small airgun array consisting of four 70 in^3 airguns.

The acoustic modeling predicted distances at which the received sound level, on an rms basis, would be 190, 180, …, 120 dB re 1 μPa rms. In the original calculations the radii were "flat weighted" and did not take into account differences in hearing sensitivity among marine mammal groups. In addition, sensitivity weighting (*M*-weighting) was applied to underwater sound levels to weight the sound at various frequencies in accordance with the hearing characteristics of different marine mammal groups, i.e., baleen whales, toothed whales, and pinnipeds. The safety radii applied during initial airgun operations were the unweighted distances predicted by the modeling. Those predicted distances were used until the actual sound field around the operating airguns was measured empirically in the field (Chapter 4).

Acoustic Measurements (Chapter 4)

Seismic and shallow hazards surveys conducted by SOI relied on the generation of underwater acoustic pulses. Greeneridge Sciences, Inc., measured the underwater sound levels produced by the acoustic equipment that was used, including airguns and shallow-hazards sources, and by the vessels involved, including both seismic and support vessels. These measurements were acquired at the start of the respective periods of operation in the Chukchi and Beaufort Seas.

Values measured by Greeneridge were compared to the values that JASCO Research Ltd. had estimated (Chapter 3) by modeling, and were used to recommend updated mitigation radii for use by marine mammal observers on the seismic and shallow hazards ships during data acquisition.

Airgun pulses were received and analyzed at distances of 0.3–34 km in the Chukchi Sea and 0.06–20.5 km in the Beaufort Sea. Logarithmic sound propagation models were fitted to pulse sound pressure levels (SPL), sound exposure levels (SEL), and peak levels. A three-string array (24 airguns totaling 3147 in^3) used in the Chukchi Sea produced the highest values but showed little aspect dependence. A one-string array (8 airguns totaling 1049 in^3) used in the Chukchi Sea showed stronger aspect dependence, with the broadside aspect producing the highest values. Received levels produced by the small airgun array used in the Beaufort Sea (4 airguns totaling 280 in^3) were generally ~15–30 dB lower (depending on distance from the source) than those in the Chukchi Sea, mainly because the Beaufort Sea array was considerably smaller.

A comparison of empirical vs. modeled SPL values showed that the empirical distances exceeded predicted distances in most (but not all) situations. For the *three-string array,* the E:P (Empirical:Predicted) ratios ranged from 1.2× to 2.0× for the 160 dB, 180 dB, and 190 dB distances, depending on aspect. E:P ratios for the 120 dB distance were higher: 2.6× to 3.2× (considering only bow and stern aspect). For the *single-string array*, E:P ratios were somewhat higher for the 190 dB and 120 dB distances than for the 160–180 dB distances, but in some cases the empirical distances were in fact less than the predicted distances (E:P < 1.0). The E:P ratios for the airgun array used in the Beaufort Sea were in general lower (better) than those obtained in the Chukchi Sea.

Broadband (10–20,000 Hz) levels of vessel sound were analyzed as a function of distance from the sound source. Received levels at 500 m distance were 125–132 dB re 1 μPa for the seismic ship *Gilavar*, and 127–135 dB for the chase vessel *Jim Kilabuk*, depending on aspect (bow, stern, broadside). Both of these ships were recorded in the Chukchi Sea. In the Beaufort Sea, the received broadband level for the tug *Henry Christoffersen* at 500 m distance was ~122 dB re 1 μPa.

Monitoring and Mitigation Methods (Chapter 5)

The main purposes of the vessel-based monitoring program were to ensure that the provisions of the IHAs issued to SOI by NMFS and USFWS were satisfied, effects on marine mammals were minimized, and residual effects on animals were documented.

Under current NMFS guidelines, "safety radii" for marine mammals around airgun arrays are customarily defined as the distances within which received pulse levels are ≥180 dB re 1 μPa (rms) for cetaceans and ≥190 dB re 1 μPa (rms) for pinnipeds. Marine mammals exposed to ≥160 dB (rms) are assumed by NMFS to be potentially subject to behavioral disturbance. For the current seismic project there has also been concern that received pulse levels as low as 120 dB (rms) may have the potential to disturb some whales. In 2006, there was a requirement to implement special mitigation measures if specified numbers of bowhead cow/calf pairs might be exposed to ≥120 dB rms or if large groups (≥12

individuals) of bowhead or gray whales might be exposed to ≥160 dB rms. Sound levels were measured in the field to determine safety and disturbance radii to be used for mitigation during seismic acquisition and shallow hazards surveys.

The primary mitigation measures that were implemented during the seismic activities in the Chukchi and Beaufort seas included ramp up, power down, and shut down of the airguns. Mitigation was implemented by marine mammal observers (MMOs) onboard the *Gilavar* and *Kilabuk* who visually monitored the safety radii, and informed the airgun operators when a marine mammal was observed within or about to enter the appropriate safety radius.

In summary, during the seismic and shallow-hazards surveys in the Chukchi and Beaufort Seas, at least one MMO onboard the source vessel (*Gilavar* or *Henry Christoffersen*) maintained a visual watch for marine mammals during all daylight hours while seismic or shallow-hazards surveys were underway. During the surveys, two visual observers were on duty for 45% of the time watches were conducted on the *Gilavar* and for 2% of the time watches were conducted on the *Henry Christoffersen*. Observers focused their search effort forward of the vessel but also searched aft of the vessel while it was underway. Watches were conducted with the naked eye, Fujinon 7 × 50 reticle binoculars, and Zeiss 20 × 60 binoculars. MMOs instructed seismic operators to power down or shut down the airguns if marine mammals were sighted within or about to enter the appropriate safety radii.

An aerial survey program was conducted in support of the shallow-hazards program in the Beaufort Sea during fall of 2006 to advise the *Henry Christoffersen* as to the presence of marine mammals in the general area of operation. During the aerial surveys, observers also collected data on the distribution and abundance of marine mammals. Nine aerial surveys were conducted between 26 Aug. and 24 Sept. SOI's only use of airguns in the Beaufort Sea in 2006 occurred on 8 Aug. and 25 Sept., and was related to site clearance and shallow hazard surveys. Aerial surveys were conducted on 23 and 24 Sept. to monitor the 120 dB zone prior to airgun operations on 25 Sept.

In general, vessel-based data were categorized as "seismic", "post-seismic", or "non-seismic". "Seismic" included all data collected from the source vessel (*Gilavar* or *Henry C.*) while the airguns were operating. Non-seismic included all data obtained before the airguns were activated (pre-seismic) or >1 or >2 h (for pinnipeds and cetaceans, respectively) after the airguns were deactivated. Data collected during post-seismic periods from 3 min to 1 h (for pinnipeds) or 2 h (for cetaceans) after cessation of seismic activity were considered either "recently exposed" (3–30 min) or "potentially exposed" (30 min to 1 or 2 h) to seismic sound levels, and were excluded from analyses. Thus, the post-seismic data (3 min to 1 or 2 h after cessation of seismic) were not included in either the "seismic" or "non-seismic" categories.

Marine mammal sightings during the "seismic" and "non-seismic" periods were used to calculate sighting rates. Sighting rates were then used to calculate the corresponding densities of marine mammals near the survey and chase ships during seismic and non-seismic periods. These densities were used to estimate the numbers of marine mammals that may have been exposed to various levels of ensonification, and to determine the estimated take by harassment.

Monitoring and Mitigation Results (Chapter 6)

Marine mammal observers aboard the *Gilavar* conducted 13,527 km and 1537 h of visual observation and MMOs aboard the *Kilabuk* conducted 14,058 km and 1251 h of visual observation, together documenting 353 sightings of 442 pinnipeds and 115 sightings of 219 cetaceans (Table ES.1). There were numerous sightings of supply and chase vessels within 5km of each of the observation vessels.

TABLE ES.1. Summary of *Gilivar*, *Kilabuk*, and *Henry Christoffersen* operations, observer monitoring effort, and marine mammal sightings during SOI marine geophysical surveys in the Chukchi and Beaufort Seas 2006.

[a] See *Acronyms and Abbreviations for description of "useable" sightings.*

A total of 8213 km and 526 hours of visual observation was conducted aboard the *Henry Christoffersen*, during which 412 sightings of 451 marine mammals were logged. The ringed seal was the most abundant species recorded. No sightings were noted during the limited periods when airguns were in use in the Beaufort Sea. Few vessels were sighted during the cruise, and only two of these approached within 5 km of the *Henry Christoffersen*.

Based on the estimated densities of marine mammals in the Chukchi Sea during this project, about 416 different individual seals, 49 walruses, and 91 cetaceans would be expected to occur within the areas ensonified to ≥190 dB re 1 μPa (rms) for pinnipeds and 180 dB re 1 μPa (rms) for cetaceans at some time during the field season. Calculated estimates for individual pinnipeds and cetaceans potentially exposed to sound levels ≥160dB re 1 μPa (rms) were 1317 and 198 respectively.

No animals observed from the *Henry Christoffersen* were potentially exposed to sound levels ≥180 dB re 1 μPa (rms). Based on calculations involving estimated densities of marine mammals, there would have been approximately 180 seals exposed to sound levels ≥160 dB re 1 μPa (rms).

On the two days of aerial surveying in support of seismic activities on the *Henry Christoffersen*, 219.4 km of transect were flown, of which 188.4 km were flown in good surveying conditions. There was one sighting of a bowhead during these surveys.

1. BACKGROUND AND INTRODUCTION[1]

Shell Offshore, Inc. (SOI), collected marine seismic data in the Chukchi and Beaufort seas during the summer of 2006 in support of potential future oil and gas leasing and development. Deep seismic acquisition for SOI was conducted in the Chukchi Sea by WesternGeco using the M/V *Gilavar*, a seismic vessel that towed an airgun array as well as hydrophone streamers to record reflected seismic data. Seismic acquisition was originally planned to be conducted in both the Chukchi and Beaufort Seas using the *Gilavar*; however, ice conditions during the 2006 field season precluded most data collection in the Beaufort Sea. Activities in the Beaufort Sea were confined to site clearance, shallow hazard surveys and geotechnical activities, that were conducted from the M/V *Henry Christoffersen*, an NTCL vessel.

Marine seismic surveys emit sound energy into the water (Greene and Richardson 1988; Tolstoy et al. 2004a,b), and have the potential to affect marine mammals given the reported auditory and behavioral sensitivity of many such species to underwater sounds (Richardson et al. 1995; Gordon et al. 2004). The effects could consist of behavioral or distributional changes, and perhaps (for animals close to the sound source) temporary or permanent reduction in hearing sensitivity. Either behavioral/distributional effects or (if they occur) auditory effects could constitute "taking" under the provisions of the U.S. Marine Mammal Protection Act (MMPA) and the U.S. Endangered Species Act (ESA), at least if the effects are considered to be "biologically significant".

Numerous species of cetaceans and pinnipeds inhabit parts of the Chukchi and Beaufort seas. Two species listed as "Endangered" under the ESA do or may occur in portions of the survey area, including bowhead whale (*Balaena mysticetus*) and perhaps the fin whale (*Balaenoptera physalus*). The National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS) share jurisdiction over the marine mammal species that were likely to be encountered during the project. USFWS manages two species occurring in the Chukchi and Beaufort Seas, the walrus (*Odobenus rosmarus*) and the polar bear (*Ursus maritimus*); NMFS manages all the other marine mammals occurring in those areas.

Other species of concern (birds) that might occur in the survey area are the spectacled (*Somateria fischeri*) and Steller's (*Polysticta stelleri*) eiders that are listed as "Threatened" under the ESA. Of the two species, spectacled eiders are more abundant, have been documented farther offshore (40 km) in the Beaufort Sea, and use some lagoon systems in the Beaufort and Chukchi seas during their molt migration.

On 16 November 2005, SOI requested that NMFS issue Incidental Harassment Authorizations (IHAs) to authorize non-lethal "takes" of marine mammals incidental to SOI's planned seismic operations in the mid- and eastern parts of the Alaskan Beaufort Sea (SOI 2005a) and in the Chukchi Sea (SOI 2005b). The IHAs were requested pursuant to Section 101(a)(5)(D) of the MMPA. A single IHA to cover activities in both the Beaufort and Chukchi seas was issued to SOI by NMFS on 5 July 2006 (Appendix A). The IHA authorized "potential take by harassment" of various cetaceans and seals during the marine geophysical cruises described in this report. On 10 Jan. 2006, SOI also requested from USFWS an IHA to authorize potential "taking" of walruses and polar bears in the Chukchi Sea. USFWS issued that IHA to SOI on 29 June 2006 (Appendix B).

This document serves to meet reporting requirements specified in the IHA. The primary purposes of this report are to describe the seismic survey in the Chukchi and Beaufort seas, to describe the associated marine mammal monitoring and mitigation programs and their results, and to estimate the

[1] Chapter 1 by R. Rodrigues, B. Haley, and D. Ireland (LGL).

numbers of marine mammals potentially exposed to levels of sound generated by the project at or above presumed effects levels.

Incidental Harassment Authorization

IHAs issued to seismic operators include provisions to minimize the possibility that marine mammals close to the seismic source might be exposed to levels of sound high enough to cause hearing damage or other injuries. During this project, sounds were generated by the *Gilavar*'s airguns, as used during the seismic study, and by several types of lower-energy sound sources on the *Henry Christoffersen* including bottom mapping and seafloor imaging sonar, a chirp sonar, a bubble pulser, and a cluster of four small airguns. No serious injuries or deaths of marine mammals were anticipated from the seismic and shallow hazards surveys, given the nature of the operations and the mitigation measures that were implemented, and no injuries or deaths were attributed to these activities. Nonetheless, the seismic survey operations described in Chapter 2 had the potential to "take" marine mammals by harassment. Behavioral disturbance to marine mammals is considered to be "take by harassment" under the provisions of the MMPA. Appendix C provides further background on the issuance of IHAs relative to seismic operations and "take".

Under current NMFS guidelines (e.g., NMFS 2005a, 2006a), "safety radii" for marine mammals around airgun arrays are customarily defined as the distances within which the received pulse levels are ≥180 dB re 1 μPa (rms)[2] for cetaceans and ≥190 dB re 1 μPa (rms) for pinnipeds. Those safety radii are based on an assumption that seismic pulses at lower received levels will not injure these mammals or impair their hearing abilities, but that higher received levels *might* have some such effects. The mitigation measures required by IHAs are, in large part, designed to avoid or minimize the numbers of cetaceans and pinnipeds exposed to sound levels exceeding 180 and 190 dB (rms), respectively. The development and implementation of the safety radii for the current project are discussed in detail in Appendix C.

Disturbance to marine mammals could occur at distances beyond the safety (shut down) radii if the mammals were exposed to moderately strong pulsed sounds generated by the airguns or perhaps by sonar (Richardson et al. 1995). NMFS assumes that marine mammals exposed to airgun sounds with received levels ≥160 dB re 1 μPa (rms) are likely to be disturbed. That assumption is based mainly on data concerning behavioral responses of baleen whales, as summarized by Richardson et al. (1995) and Gordon et al. (2004). Dolphins and pinnipeds are generally less responsive than baleen whales (e.g., Stone 2003; Gordon et al. 2004), and 170 dB (rms) may be a more appropriate criterion of potential behavioral disturbance for those groups (LGL Ltd. 2005a,b). In general, disturbance effects are expected to depend on the species of marine mammal, the activity of the animal at the time of disturbance, distance

[2] "rms" means "root mean square", and represents a form of average across the duration of the sound pulse as received by the animal. Received levels of airgun pulses measured on an "rms" basis (sometimes described as Sound Pressure Level, SPL) are generally 10–12 dB lower than those measured on the "zero-to-peak" basis, and 16–18 dB lower than those measured on a "peak-to-peak" basis (Greene 1997; McCauley et al. 1998, 2000a,b). The latter two measures are the ones commonly used by geophysicists. Unless otherwise noted, all airgun pulse levels quoted in this report are rms levels. Received levels of pulsed sounds can also be described on an energy or "Sound Exposure Level" basis, for which the units are dB re $(1\ \mu Pa)^2 \cdot s$. The SEL value for a given airgun pulse, in those units, is typically 10–15 dB less than the rms level for the same pulse (Greene 1997; McCauley et al. 1998, 2000a,b), with considerable variability (Madsen et al. 2006; see also Chapter 4 of this report). SEL (energy) measures may be more relevant to marine mammals than are rms values, but the current regulatory requirements are based on rms values.

from the sound source, the received level of the sound and the associated water depth. Some individuals may exhibit behavioral responses at received levels somewhat below the nominal 160 or 170 dB (rms) criteria, but others may tolerate levels somewhat above 160 or 170 dB without reacting in any substantial manner. For example, migrating bowhead whales in the Alaskan Beaufort Sea show avoidance at received levels substantially lower than 160 dB re 1 μPa_{rms} (Miller et al. 1999; Richardson et al. 1999). In contrast, bowhead whales on the summer feeding grounds tolerate received levels of 160 dB or sometimes more (Richardson et al. 1986; G. Miller et al. 2005). Beluga whales also show avoidance at levels below 160 dB (G. Miller et al. 2005).

A notice regarding the proposed issuance of an IHA for the survey in the Chukchi and Beaufort seas was published by NMFS in the *Federal Register* on 3 May 2006 and public comments were invited (NMFS 2006a). On 24 Aug. 2006, NMFS published a second notice in the *Federal Register* to announce the issuance of the IHA (NMFS 2006b). The second notice responded to 32 comments received by NMFS during the 30-day public comment period. A copy of the IHA is included in this report as Appendix A.

The IHA issued by NMFS to SOI authorized harassment "takes" of one ESA-listed species (bowhead whale) as well as several non-listed species: gray (*Eschrichtius robustus*), killer (*Orcincus orca*), and beluga (*Delphinapterus leucas*) whales, harbor porpoises (*Phocoena phocoena*), and ringed (*Phoca hispida*), spotted (*Phoca largha*), and bearded (*Erignathus barbatus*) seals.

NMFS granted the IHA to SOI on the assumptions that

- the numbers of whales and seals potentially harassed (as defined by NMFS criteria) during seismic operations would be "small",
- the effects of such harassment on marine mammal populations would be negligible,
- no marine mammals would be seriously injured or killed,
- there would be no unmitigated adverse effects on the availability of marine mammals for subsistence hunting in Alaska, and
- the agreed upon monitoring and mitigation measures would be implemented.

USFWS determined in 2006 that proponents of arctic seismic projects should operate under IHAs issued by USFWS. The process of obtaining an IHA from USFWS was very similar to that of obtaining one from the NMFS. On 10 January 2006, SOI requested an IHA from USFWS for the incidental taking of walruses and polar bears in conjunction with seismic activities in the Chukchi Sea (SOI 2006). A notice regarding the proposed issuance by USFWS of an IHA for the survey in the Chukchi Sea was published in the *Federal Register* on 8 May 2006 and public comments were invited (USFWS 2006). This IHA was issued to SOI by USFWS on 29 June 2006. USFWS did not publish a second notice in the *Federal Register* to announce the issuance of the IHA. A copy of the USFWS IHA is included in this report as Appendix B. The IHA required SOI to observe a 190 dB safety radius for walruses and polar bears.

Mitigation and Monitoring Objectives

The objectives of the mitigation and monitoring program were described in detail in SOI's IHA applications (SOI 2005a,b, 2006) and in the IHA issued by NMFS to SOI (Appendix A). Explanatory material about the monitoring and mitigation requirements was published by NMFS and USFWS in the *Federal Register* (NMFS 2006a,b; USFWS 2006).

The main purpose of the mitigation program was to avoid or minimize potential effects of SOI's seismic survey on marine mammals. This required that shipboard personnel detect marine mammals within or about to enter the designated safety radii (190 dB for pinnipeds and 180 dB for cetaceans), and in such cases initiate an immediate power down (or shut down if necessary) of the airguns. A power down involves reducing the source level of the operating airguns, in this case by reducing the air volume. A shut down involves temporarily terminating the operation of all airguns. An additional mitigation objective was to detect marine mammals within or near the safety radii prior to starting the airguns, or during ramp up toward full power. In these cases, the start of airguns was to be delayed or ramp up discontinued until the safety radius was free of marine mammals insofar as this can be determined visually for a period of 30 minutes (see Appendix A and Chapter 5).

In 2006 mitigation was also required, as specified by the IHA, at the 160 dB isopleth. This area was monitored by the chase boat that accompanied the seismic vessel. Power down of the seismic airgun array was required if an aggregation of 12 or more non-migratory bowhead or gray whales was detected ahead of, or perpendicular to, the seismic vessel track and within the 160 dB isopleth. Monitoring of the 120 dB isopleth around the seismic vessel(s) was also required after 25 September in the Chukchi Sea and after 1 September in the Beaufort Sea. Power down would be required if 4 migratory cow/calf pairs were detected within the surveyed 120 dB isopleth.

The primary objectives of the monitoring program were as follows:

1. provide real-time sighting data needed to implement the mitigation requirements;
2. estimate the numbers of marine mammals potentially exposed to strong seismic pulses; and
3. determine the reactions (if any) of marine mammals potentially exposed to seismic sound impulses.

Specific mitigation and monitoring objectives identified in the IHAs are described in Appendices A and B. Mitigation and monitoring measures that were implemented during the activities in the Chukchi and Beaufort seas are described in detail in Chapter 5.

This 90-day report describes the methods and results for the monitoring work specifically required to meet the above primary objectives. Various other marine mammal and acoustic monitoring and research programs not specifically tied to the above objectives were also implemented by SOI (or by SOI plus other industry operators) in the Chukchi and/or Beaufort Seas during 2006. Results of those additional efforts are, for the most part, not mentioned in this 90-day report. Those additional results will be reported at a later date.

Report Organization

The primary purpose of this report is to describe the 2006 seismic survey activities in the Chukchi and Beaufort seas including the associated monitoring and mitigation programs, and to present results as required by the IHAs (Appendices A and B). This report includes six chapters:

1. background and introduction (this chapter);
2. description of SOI's seismic and site clearance studies;
3. sound source and propagation modeling prior to the field season;
4. sound source measurements during the field season;
5. description of the marine mammal monitoring and mitigation requirements and methods,

including safety radii; and

6. results of the marine mammal monitoring program, including estimated numbers of marine mammals potentially "taken by harassment".

Those chapters are followed by Acknowledgements and Literature Cited sections.

In addition, there are nine Appendices that provide copies of relevant documents and details of procedures that are more-or-less consistent during seismic surveys where marine mammal monitoring and mitigation measures are in place. These procedural details are only summarized in the main body of this report. The Appendices include

A. a copy of the IHA issued by NMFS to SOI for this study;

B. a copy of the IHA issued by USFWS to SOI for this study;

C. background on development and implementation of safety radii;

D. characteristics of the *Gilavar* and *Henry Christoffersen*;

E. details on visual and acoustic monitoring, mitigation, and data analysis methods;

F. conservation status and densities of marine mammals in the project region;

G. monitoring effort and list of marine mammals seen or heard during this cruise;

H. marine mammal sightings with power downs and shut downs during the seismic activities;

I. marine mammal density estimates for the project area.

2. SEISMIC SURVEYS DESCRIBED[3]

Chukchi Sea

The *Gilavar* was used as the source vessel during SOI's activities in the Chukchi Sea in 2006. The *Gilavar* was accompanied by the *Jim Kilabuk*, an icebreaker-class support vessel (chase vessel). Two other support vessels were also used in the Chukchi Sea at various times during the field season. The *Gulf Provider* was used as a supply vessel for transfer of personnel during crew changes, for fuel transfers to the *Kilabuk*, and to resupply the *Gilavar* with equipment and supplies. In addition, the *Peregrine*, a flat-bottom landing craft with minimal draft, was used for transfer of personnel and equipment from shore areas to the *Gulf Provider*. Appendix D contains a description of the vessels used during the seismic activities. These four vessels operated in accordance with the provisions of a Conflict Avoidance Agreement (CAA) between the seismic industry, the Alaska Eskimo Whaling Commission (AEWC), and the Whaling Captains Associations with respect to subsistence activities including but not limited to the hunts for bowhead and beluga whales. The objective of the CAA was to provide avoidance and other mitigation guidelines to be followed by industry participants working in or transiting the vicinity of active whaling crews. Under the terms of the CAA, communication centers were established at Barrow and Deadhorse, and Call Centers at Pt. Hope, Pt. Lay, Wainwright, and Kaktovik. The CAA outlined a communication program and specified times and areas to be surveyed in order to avoid any possible conflict with the subsistence hunts.

Operating Areas, Dates, and Navigation

The proposed deep seismic survey was originally scheduled to occur in two phases. Phase one commenced in July when sea ice conditions allowed access to the Chukchi Sea. Operations were originally planned to continue there until some date in late summer when the *Gilavar* and *Kilabuk* were to transit to the Beaufort Sea to conduct seismic surveys on Shell lease-holdings in the mid- and eastern parts of the Alaskan Beaufort Sea. Heavy ice conditions delayed the date when operations could have transferred to the Beaufort Sea, and seismic operations continued in the Chukchi Sea. During September, SOI decided not to attempt to conduct deep seismic exploration in the Beaufort Sea during 2006 due to high concentrations of ice and other operational considerations. The *Gilavar*'s airguns and streamers were retrieved on 19 September and the *Gilavar* departed southward from the project area and left the Chukchi Sea on 23 September.

The geographic region where the deep seismic survey occurred was located in the Chukchi Sea MMS OCS Program Area designated as Chukchi Sea Sale 193 (1989) and in the proposed 2002–2007 Chukchi Sea Program Area (see Fig. 2.1). Since the Chukchi Sea deep seismic program was conducted as a pre-lease activity, the exact locations where operations occurred remains confidential for business reasons. That is, the seismic data acquired in 2006 will be used by SOI to identify leases on which it may bid in a forthcoming competitive lease sale. However, in general, seismic acquisition occurred in the Chukchi Sea well offshore from the Alaska coast in OCS waters averaging greater than 40 meters (m) or 131 ft deep and outside the polynya zone.

The *Gilavar* left Dutch Harbor on 7 July to travel to the project area, and entered the Chukchi Sea on 10 July. Operations were then delayed due to ice conditions in the planned operating areas and to avoid potential disruption of the Pt. Lay beluga hunt. SOI's seismic contractor began deploying the seismic acquisition equipment on 21 July. After deployment of the airguns, the underwater sounds

[3] Chapter 2 by R. Rodrigues, B. Haley, and D. Ireland (LGL).

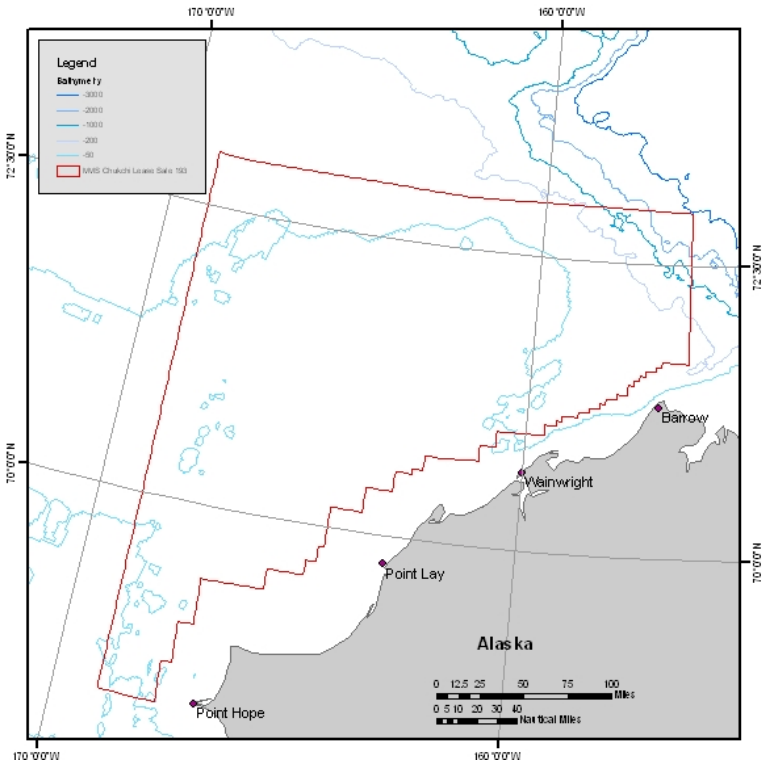

FIGURE 2.1. Location of the proposed MMS Chukchi Sea Lease Sale 193 within which SOI's 2006 high-energy seismic activities were conducted.

produced by the airgun array were recorded and analyzed to verify or refine the various radii to be used for mitigation purposes during the exploration activities (see Chapter 4 below). Those radii had been predicted prior to the field season via acoustic modeling procedures (see Chapter 3), but site-specific empirical measurements were required to confirm or refine the predictions. The airgun sounds were recorded as a function of airgun configuration, distance, and aspect on 21 and 22 July, and safety and disturbance radii based on these measurements were determined within 72 hrs. Seismic acquisition began on 27 July 2006 and continued through most of the field season until 19 September. SOI then determined that ice conditions and other operational considerations precluded continuation of the exploration program or a transition of the program into the Beaufort Sea, and seismic activities were terminated. SOI completed ~5297.4 km (3291.7 statute mi) of deep-seismic survey line in the Chukchi Sea in 2006.

Throughout the survey the *Gilavar's* position, speed, and water depth were logged digitally every ~60 s. In addition, the position of the *Gilavar*, water depth, and information on the airgun array were logged for every airgun shot while the *Gilavar* was on a seismic line and collecting geophysical data. The geophysics crew kept an electronic log of events, as did the marine mammal observers (MMOs) while on duty. The MMOs also recorded the number and volume of airguns that were firing when the *Gilavar* was offline (e.g., prior to shooting at full volume) or was online but not recording data (e.g., during airgun or computer problems).

Airgun Description

SOI used WesternGeco's 3147 in^3 3-string array of Bolt airguns for its 3–D seismic survey operations in the Chukchi Sea. WesternGeco's source array was composed of 3 identically-tuned Bolt airgun sub-arrays, each with 8 airguns and a total volume of 1049 in^3, operated at an air pressure of 2000

psi. Each string was 15 m in length, and each string was 8 m from the adjacent string(s). The individual airguns ranged in volume from 30 to 235 in^3, and each string included two 235 in^3 and two 125 in^3 airguns in 2-gun clusters. This energy source was towed approximately 245 m behind the *Gilavar*. The system also included 6 hydrophone streamers 4200 m in length and spaced 100 m apart, which recorded reflected sound energy. In general, the *Gilavar* towed this system along a predetermined survey track although adjustments were made during the course of the field season in accordance with ice conditions.

Air compressors aboard the *Gilavar* were the source of high pressure air used to operate the airgun arrays. Seismic pulses were emitted at intervals of 25 m (~10 sec) while the *Gilavar* traveled at a speed of 4 to 5 knots (7.4–9.3 km/h). The airgun arrays were towed at a depth of 6 m and were 8 m apart. Characteristics of the airgun arrays are detailed in Appendix D.

Beaufort Sea—Vessel-based Component

In addition to deep seismic surveys in the Chukchi Sea, SOI also conducted site clearance and shallow hazards surveys of potential exploratory drilling locations within SOI's lease areas in the Beaufort Sea as required by MMS regulations. Before drilling can begin, a site clearance survey and analysis is necessary to identify and/or evaluate potentially hazardous or otherwise sensitive conditions and sites at or below the seafloor that could affect the safety or appropriateness of operations. Examples of such conditions include subsurface faults, fault scarps, shallow gas, steep-walled canyons and slopes, buried channels, current scour, migrating sedimentary bedforms, ice gouging, permafrost, gas hydrates, unstable soil conditions, pipelines, anchors, ordnance, shipwrecks, or other geophysical or man-made features.

Offshore site clearance surveys use various geophysical methods and tools to acquire graphic records of seafloor and sub-seafloor geologic conditions. The data acquired and the types of investigations outlined below are performed routinely for most exploratory drilling and production facilities in marine areas, and for submarine pipelines, port facilities, and other offshore projects. High-resolution geophysical data such as two-dimensional, high-resolution multi-channel seismic, medium penetration seismic, subbottom profiler, side scan sonar, multibeam bathymetry, magnetometer, and possibly piston core sediment sampling are typical types of data acquired. These data are interpreted to define geologic, geotechnical and archeological conditions at the site and to assess the potential engineering significance of these conditions. The following section provides a brief description of the operations and instrumentation used during SOI's 2006 Beaufort Sea site clearance program insofar as they may impact marine mammals.

Operating Areas, Dates, and Navigation

The site clearance surveys were confined to very small specific areas within defined OCS blocks (Fig. 2.2). The surveys were conducted from the M/V *Henry Christofferson*. This vessel is 47 m (153 ft) long and the gross tonnage is 783 metric tons. It is powered by four Caterpillar V16 D399 diesel engines and can travel at a speed of 14 knots (see Appendix D). Small geophysical survey sources with limited energy output were employed to measure bathymetry, topography, geohazards, and other seabed characteristics. The strongest sound source was a cluster of four 70 in^3 airguns, which was used during the sound source measurements. Two 70 in^3 airguns were used during a deeper site clearance survey on 25 Sept. Chapter 4 describes results of measurements of sounds from this and other acoustical sources used during site clearance operations.

Measurements of sounds from the 4-airgun array and from other acoustic sources on the *Henry C.* were conducted on 8 Aug. in the Beaufort Sea east of Kaktovik (see Chapter 4 for details). The sound sources (including the cluster of 4 airguns) were operated for 2.5 hours on this date. Between

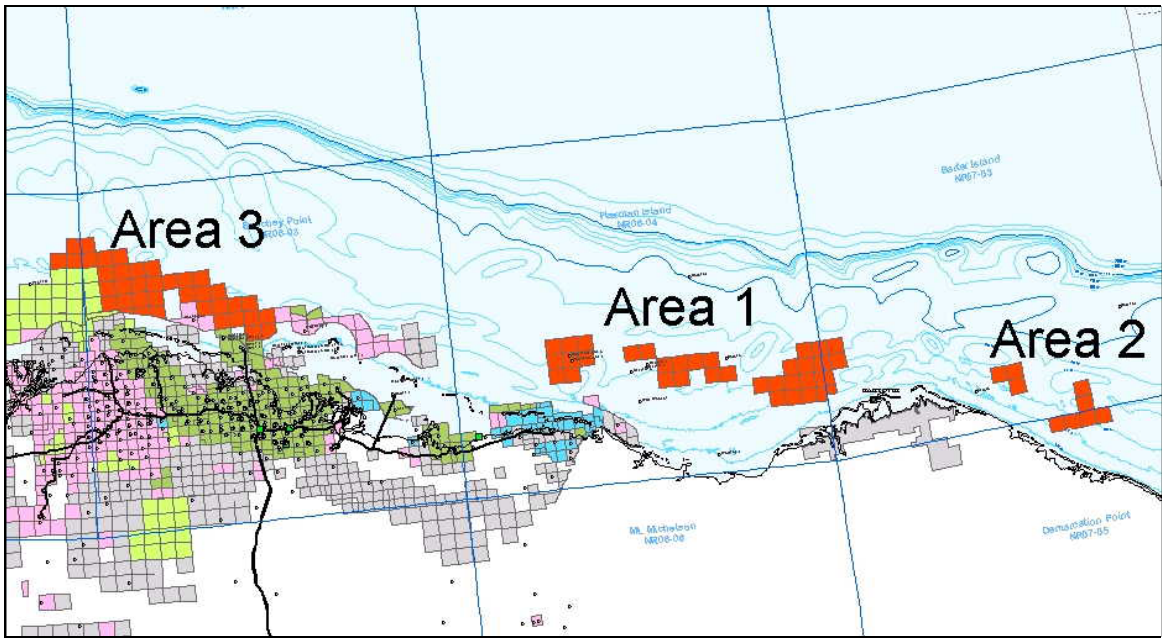

FIGURE 2.2. Location of SOI lease holdings in the Alaskan Beaufort Sea.

8 Aug. and 2 Oct. 2006, on an intermittent basis as allowed by ice and weather conditions, various types of site clearance surveys were conducted from the *Henry C.* These operations were in specific nearshore areas ranging from east of Kaktovik west to Thetis Island near the Colville River Delta (Fig. 2.2). Site clearance survey activities occurred on ~23 days during this period. However, during that period the airgun cluster (2 airguns) was operated only once for ~12 hrs on 25 Sept. At all other times during surveys, the acoustical sources in use were lower-energy medium- and high-frequency sources as described below. On days when surveys did not occur, the *Henry Christoffersen* was usually transiting to a new site or anchored while waiting for bad weather or ice conditions to subside.

Throughout the survey the *Henry Christoffersen*'s position, speed, and water depth were logged digitally every ~60 s. In addition, the position of the *Henry C.*, water depth, and information on the output of the airgun array or other geophysical tools were logged during all site clearance activities. The geophysics crew kept an electronic log of events, as did the marine mammal observers (MMOs) while they were on duty.

Geophysical Tools for Site Clearance

An airgun cluster consisting of four 70-in^3 airguns was planned for use during site clearance operations to locate potential hazards, such as gas deposits, at relatively shallow locations. The results of the source measurements indicated to the operators that the use of the 4-airgun array was excessive for their needs. Therefore, a pair of 70-in^3 airguns was the sound source used during the ~12-h of airgun operations on 25 Sept.

Several other lower-energy acoustic sources were operated for shallow-penetration subbottom surveys and to map the bottom. A bubble pulser operating at frequencies near 400 Hz was used for medium penetration and a chirp sonar operating at 2–7 and 8–23 Hz was used for shallow penetration. Other acoustic sources used to map the seafloor included a multibeam bathymetric sonar operating at 240

kHz and a side-scan sonar operating at 190–210 kHz. Characteristics of this equipment are described in more detail in Appendix D.

Beaufort Sea—Aerial Component

SOI originally intended to conduct aerial surveys in the Beaufort Sea in the summer (July to late Aug.) to collect pre-seismic baseline data and to conduct fall surveys (late Aug. to Oct.) as part of the monitoring and mitigation effort associated with seismic survey activities. Logistical problems early in the summer season precluded SOI's ability to conduct summer aerial surveys, and since SOI did not conduct any deep seismic acquisition from the *Gilavar* in the Beaufort Sea in 2006, the aerial surveys in the Beaufort Sea were only in support of the shallow hazards and site clearance activities conducted from the *Henry Christoffersen*.

A series of 8 north–south transect lines was established to monitor the project area in Camden Bay where SOI planned to conduct shallow hazard and site clearance surveys using their 240 in^3 airgun array (Fig. 2.3). Nine aerial surveys of the project area were conducted using a Twin Otter aircraft flown at 1000 ft above ground level at an airspeed of approximately 120 knots. The first 7 surveys, conducted between 26 Aug. and 14 Sept., were pre-seismic surveys intended to collect baseline data on the distribution and abundance of marine mammals in the project area. Surveys were flown on 23 and 24 Sept. to monitor the 120 dB zone prior to seismic activities on 25 Sept.

3. ACOUSTIC MODELING[4]

INTRODUCTION

Shell Offshore, Inc. (SOI), conducted seismic exploration activities in the Chukchi Sea and shallow hazards surveys in the Alaskan Beaufort Sea during summer 2006. Prior to conducting these activities SOI contracted with JASCO Research Ltd. to provide an acoustic model to estimate the extent of ensonification from the seismic acquisition and shallow hazards survey equipment in the Chukchi and Beaufort seas. The purpose of the modeling was

- to characterize the acoustic environment in the areas of the Chukchi and Beaufort seas where the seismic and shallow hazards programs were to be conducted,
- to predict the anticipated source characteristics of the emitted sounds, and
- to provide estimates of the received sound levels as a function of distance and aspect around the various acoustic sources when operating in the planned study regions.

Sound propagation modeling was performed for six locations, three in the Chukchi Sea and three in the Beaufort Sea, to provide predictions representative of the areas over which seismic exploration and shallow hazards surveys were to occur. The particular type of model used is state-of-the-art. It takes account of the specific configurations of the planned airgun arrays, and also allows for the anticipated effects of local environmental conditions on propagation of sound. Those propagation effects can have strong influences on received sound levels and other acoustic parameters, especially in shallow-water environments such as those where SOI's 2006 programs were to occur. The specific modeling approach used in this study has been subject to expert review by an IUCN scientific panel (Reeves 2005). Model input parameters, notably bathymetry, seabed properties, and sound velocity profiles for the water column, were chosen to be appropriate for the respective geographic regions and seasons modeled. The site locations for modeling were near the prospect or in areas similar with respect to the parameters mentioned above.

Use of acoustic modeling techniques to estimate the noise footprint associated with the seismic and shallow hazards survey activities provided a basis for planning the mitigation procedures that were implemented to minimize impacts of SOI's project on marine mammals. However, the project plans also provided for field measurements of the actual sound levels and characteristics early in the period of operation in both the Chukchi and Beaufort Seas. Results of those field measurements are described in Chapter 4 of this report. The modeling and field measurement programs were complementary to one another.

The main sound sources that were considered in this modeling study included three airgun arrays consisting of one, two and three strings of airguns with 8 airguns per string (i.e., totals of 8, 16 and 24 airguns with a total volumes of 1049 in^3, 2098 in^3 and 3147 in^3 respectively). Also considered in the modeling were three potential shallow hazards survey sources. These were individual airguns of 10 in^3 and 20 in^3 volume, and a small airgun array consisting of four 60 in^3 airguns for a total volume of 240 in^3. The 24-airgun 3147 in^3 configuration that was modeled closely matched the actual airgun configuration used by SOI for the Chukchi Sea seismic survey. The actual airgun configuration for the limited airgun operations during the 2006 shallow-hazards survey in the Beaufort Sea was a 4-airgun 280 in^3 array, slightly larger than the configuration that was modeled. Given that peak pressure from an airgun source increases in proportion

[4] Summarized by LGL from a detailed technical report (Austin et al. 2006b; 21 August 2006 version 3) by JASCO Research Ltd. for Shell Offshore Inc.

to the cube root of the source volume, an increase from 240 to 280 in^3 would have minimal effect on the received sound levels at any distance; at any location, the change would be less than 1 dB.

JASCO's modeling is a two-stage process. *(1)* A proprietary airgun array source-level model was used to characterize the sounds emitted by individual elements within each airgun array, and by the array as a whole. This source model took account of the specifications and spacing of the individual airguns planned for use during the 2006 seismic and shallow-hazards programs. *(2)* The modeled source levels were incorporated into an N×2-D sound propagation model, JASCO's Marine Operations Noise Model (MONM), to estimate the sound field as a function of distance and direction from each source. From this, JASCO estimated the ranges corresponding to the various safety and disturbance criteria that are typically applied during seismic programs conducted under Incidental Take Authorizations issued by the National Marine Fisheries Service (e.g., the 190, 180 and 160 dB re 1 μPa rms distances). Other distances of interest, including the 170 dB and 120 dB distances, were also estimated. This Chapter summarizes the methods and results of the sound source modeling. This summary of the modeling effort and results is based on JASCO's detailed technical report on the modeling, by Austin et al. (2006b).

JASCO SOURCE MODEL

JASCO currently employs a full-waveform airgun array signature model, called AASM, to compute the source level and directionality of airgun arrays (MacGillivray et al. 2004). The source signature model numerically simulates the oscillation and radiation of a collection of airgun bubbles. The theory of the airgun array model is beyond the scope of this report but is based on the pioneering work of Ziolkowski (1970) who first modeled the pressure waveforms of seismic airguns, with additional physics to account for pressure interactions between airguns, port throttling, bubble damping and GI-gun behavior, as described by such authors as Dragoset (1984), Laws et al. (1990), and Landro (1992). The source model includes four empirical parameters that are tuned so that the model output matches observed airgun behavior. The model parameters were fitted to a large library of real airgun data using a "simulated annealing" global optimization algorithm. The airgun data used in the optimization were obtained from a previous study (Racca and Scrimger 1986) that measured the signatures of Bolt airguns, ranging in volume from 5 in^3 to 185 in^3.

The output of the airgun array source model is a set of "notional" signatures for the individual array elements (i.e., the airguns). The notional signatures are the pressure waveforms of the individual guns, which are summed together with the appropriate phase delays to obtain the far-field source signature of the array (Parkes and Hatton 1986). The far-field array signature, in turn, is filtered into 1/3-octave pass bands to compute the source level of the array as a function of frequency band and propagation azimuth.

Seismic Sources Modeled

The three seismic airgun arrays modeled in this study were configured as per the specifications for the three arrays planned for use during the seismic program. One array had total volume 3147 in^3 and consisted of three sub-strings, with eight guns each. Each string of 8 airguns was 15 m in length, and the strings were spaced 8 m apart for total array dimensions of 16 m (cross-track) by 15 m (along-track). Individual airguns in each string ranged in volume from 30 in^3 to 235 in^3, and each string included two 235 in^3 airguns in a cluster. The second airgun array had a total volume of 2098 in^3 and consisted of two identical sub-strings as described above, with eight guns each (array dimensions 8 m cross-track by 15 m along track). The third airgun array had a total volume of 1049 in^3 and consisted of one 15-m-long sub-string (as described above) with eight guns total.

All three arrays were modelled using AASM to compute notional source signatures and 1/3-octave band source levels as a function of azimuth angle. The source depth was set at the anticipated operating depth of 6 m. Broadside and endfire overpressure signatures and corresponding power spectrum levels were calculated.

Shallow Hazards Sources Modeled

Shallow hazards surveying was to be accomplished using a source such as an individual airgun or a small airgun array, an echosounder, a bubble pulser, chirp sonar (sub-bottom profiler), a multibeam sonar, or a sidescan sonar. The source signatures of a single airgun of two different sizes (10 in^3 and 20 in^3) and of a small airgun array (4 airguns totaling 240 in^3) were modeled for this report. The 4-airgun source was the strongest source anticipated for use during the shallow hazards program. Sounds from a bubble pulser and chirp sonar were not modeled in advance of the field season, but were measured in the field at the start of the shallow-hazards program (Chapter 4). The multibeam and sidescan sonars operate at very high frequencies (240 kHz and 190–210 kHz, respectively) that are too high to be of concern for the marine mammal species that inhabit the Beaufort Sea and were not considered for this report.

SOUND PROPAGATION MODELING METHODOLOGY

Acoustic models can be used to predict sound transmission loss in defined environments. Subtracting the modeled transmission loss values (in decibels) from estimated source levels provides estimates of received levels at defined receiver positions. The transmission loss model used in this study is JASCO Research's MONM acoustic model. Airgun array source levels, predicted with AASM, were input to MONM and received levels were predicted.

MONM computes the expected received sound levels in terms of energy flux density (EFD), also referred to as Sound Exposure Level (SEL), for 3-dimensional range-varying acoustic environments. It does so by utilizing a wide-angled parabolic equation (PE) solution to the acoustic wave equation. The parabolic equation code in MONM is based on the Naval Research Laboratory's Range-dependent Acoustic Model (RAM), which has been extensively benchmarked for accuracy and is widely employed in the underwater acoustics community (Collins 1993). MONM computes acoustic fields in 3-D by modeling transmission loss along radial traverses at evenly-spaced angles covering a 360º swath from the source (known as N×2-D modeling). MONM employs several kinds of environmental data, including bathymetry, sound speed profiles, and geoacoustic profiles, and samples the acoustic environment every 50 meters in range along model traverses. MONM handles frequency dependence by computing acoustic transmission loss in 1/3-octave bands from 10 Hz to 2 kHz. MONM computes received sound pressure level by combining transmission loss with frequency-dependent source levels. MONM's sound level predictions have been validated against experimental data from shallow-water environments, and in those prior applications have proven to be highly accurate (Hannay 2004).

Environmental data for each modeling location, such as bathymetry, water column profiles, and geology were obtained from various sources for the appropriate times of year. For locations in the Chukchi Sea, environmental data appropriate to the month of July were used. For Beaufort Sea locations, data for the month of August were used.

SOUND LEVEL RADII

Seismic Airgun Array

MONM computes the received energy level of an airgun pulse in SEL units, expressed in dB re 1 $\mu Pa^2 \cdot s$ (e.g., Fig. 3.1), and does not directly compute peak or rms sound pressure level (SPL, in dB re 1 µPa rms). However, current U.S. regulatory requirements are based on the SPL (rms) metric, i.e., the root-mean-square sound pressure level calculated over the interval within 90% of the pulse energy reaches the receiver (sometimes abbreviated as "90% rms"). The rms value for a received airgun pulse is a function not only of distance, but also of the extent to which the pulse duration has been extended by propagation effects. To compute sound pressure levels directly, allowing for dispersion phenomena, would require calculation times that would be prohibitive for large geographic areas like those considered in the current study.

In order to convert the MONM results (in SEL units) to rms values compatible with the U.S. regulatory requirements, the "Fourier synthesis" technique as described in Jensen et al. (1994) has been used to develop a conversion procedure. For each source configuration and modeling site, the result is a set of predicted radii at which the received sound level, on an rms basis, would be 190, 180, …, 120 dB re 1 µPa rms. Table 3.1 shows the predictions for the three modeling sites in the Chukchi Sea and the three airgun configurations that were considered (1-, 2- and 3-string; 8, 16 and 24 airguns; 1049, 2098 and 3147 in^3). These values

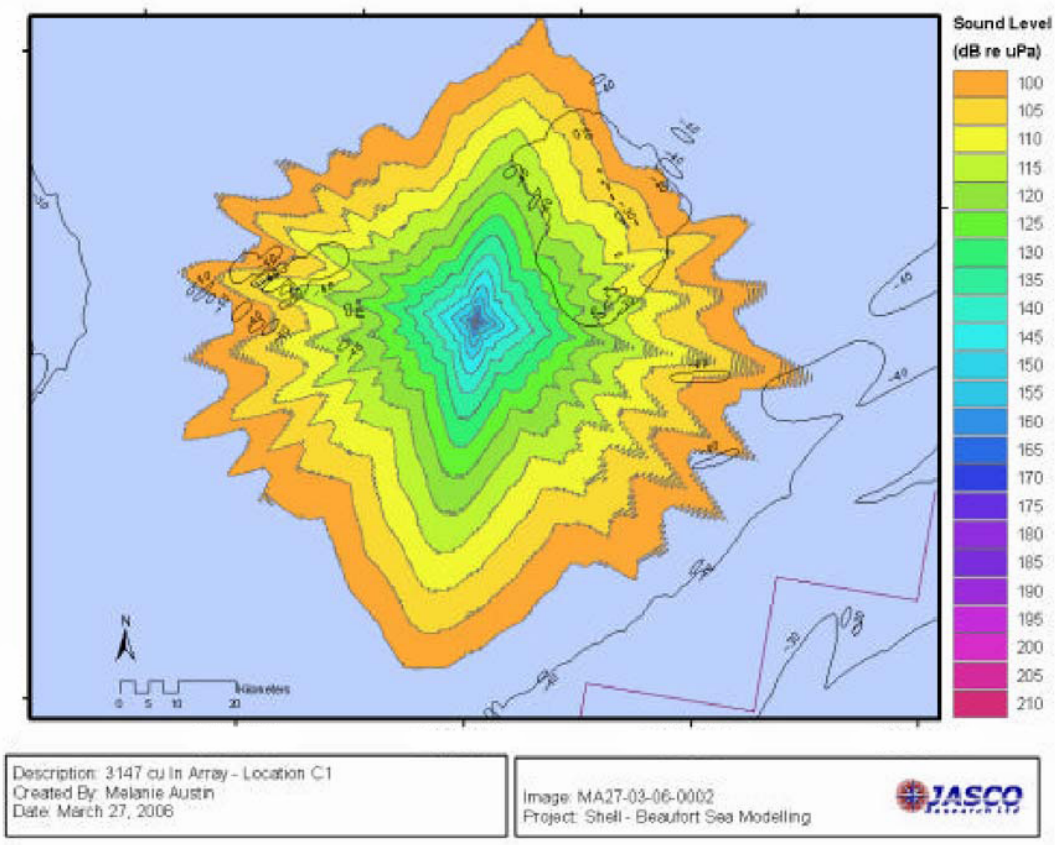

FIGURE 3.1. Map of predicted received levels on an energy basis, in Sound Exposure Level (SEL) units, at 10 m depth for a 3147 in^3 airgun array being towed approximately East–West at source location C1.

TABLE 3.1. Predicted rms radii, in kilometers, for the 1049 in^3, 2098 in^3 and 3147 in^3 airgun arrays operating at 3 modeled locations in the Chukchi Sea.

90% rms [dB re μPa]	C1			C2			C3

140	9.9	12.03	12.55	9.73	12.47	13.24	13.02	16.86	17.28
150	6.2	7.56	7.95	5.79	7.72	8.16	7.53	10.05	10.51
160	3.59	4.25	4.53	3.18	4.40	4.62	3.80	5.25	5.67
170	1.73	2.05	2.19	1.67	2.10	2.20	1.88	2.17	2.44
180	0.61	0.76	0.81	0.64	0.80	0.85	0.58	0.77	0.82
190	0.09	0.22	0.23	0.11	0.11	0.13	0.05	0.23	0.23

are derived based on predicted received levels at a large number of grid points (e.g., Fig. 3.1), and there is some variability in the specific distance at which the received sound level would be expected to diminish to any given level. The tabulated distances for a given level (e.g., 180 dB rms) are those encompassing 95% of the locations at which the received level is expected to be ≥180 dB re 1 μPa rms.

The sound from the main 3-string airgun array is predicted to be ~5 dB stronger in the broadside direction than in the endfire direction (e.g., Fig. 3.1). This aspect dependence is predicted to be larger for a single string array than for a 2- or 3-string array (e.g., Fig. 3.2).

The radii calculated in Table 3.1 are "flat weighted" and do not take into account differences in hearing sensitivity among marine mammal groups. Sensitivity weighting (*M*-weighting) was applied to underwater sound levels to weight the sound at various frequencies in accordance with the hearing characteristics of different marine mammal groups. Weighting sound levels in this way decreases the contribution to the overall received level by sound energy in frequency bands outside the frequency range where the mammal in question hears well. Weighting curves appropriate for various categories of marine mammals exposed to strong sounds were first presented by the Advisory Committee on Acoustic Impacts on Marine Mammals in April 2004 (Gentry et al. 2004). They have subsequently been presented in more detail by J. Miller et al. (2005) and in Southall et al. (submitted).

Baleen whales hear well at low frequencies, which are the dominant frequencies in airgun pulses, and frequency weighting would not significantly affect the estimated 190, 180, …, 120 dB rms radii for baleen whales. However, pinnipeds and especially the "mid-frequency cetaceans" (like beluga whales) do not hear as well at low frequencies, and frequency weighting appropriate to those groups was expected to result in reduced effective radii for them. Tables 3.2 and 3.3 show how frequency weighting reduces the predicted rms radii for those two groups, as compared with flat weighting (Table 3.1).

Shallow Hazards Survey Sources

10 in^3 and 20 in^3 Airgun Sources

During the planning phase for this project, it was considered possible that an individual airgun might be used to survey for shallow hazards. It was anticipated that the largest-volume single airgun that might be used in this way would be 20 in^3. Alternatively, a single 10 in^3 airgun might be used. Either of

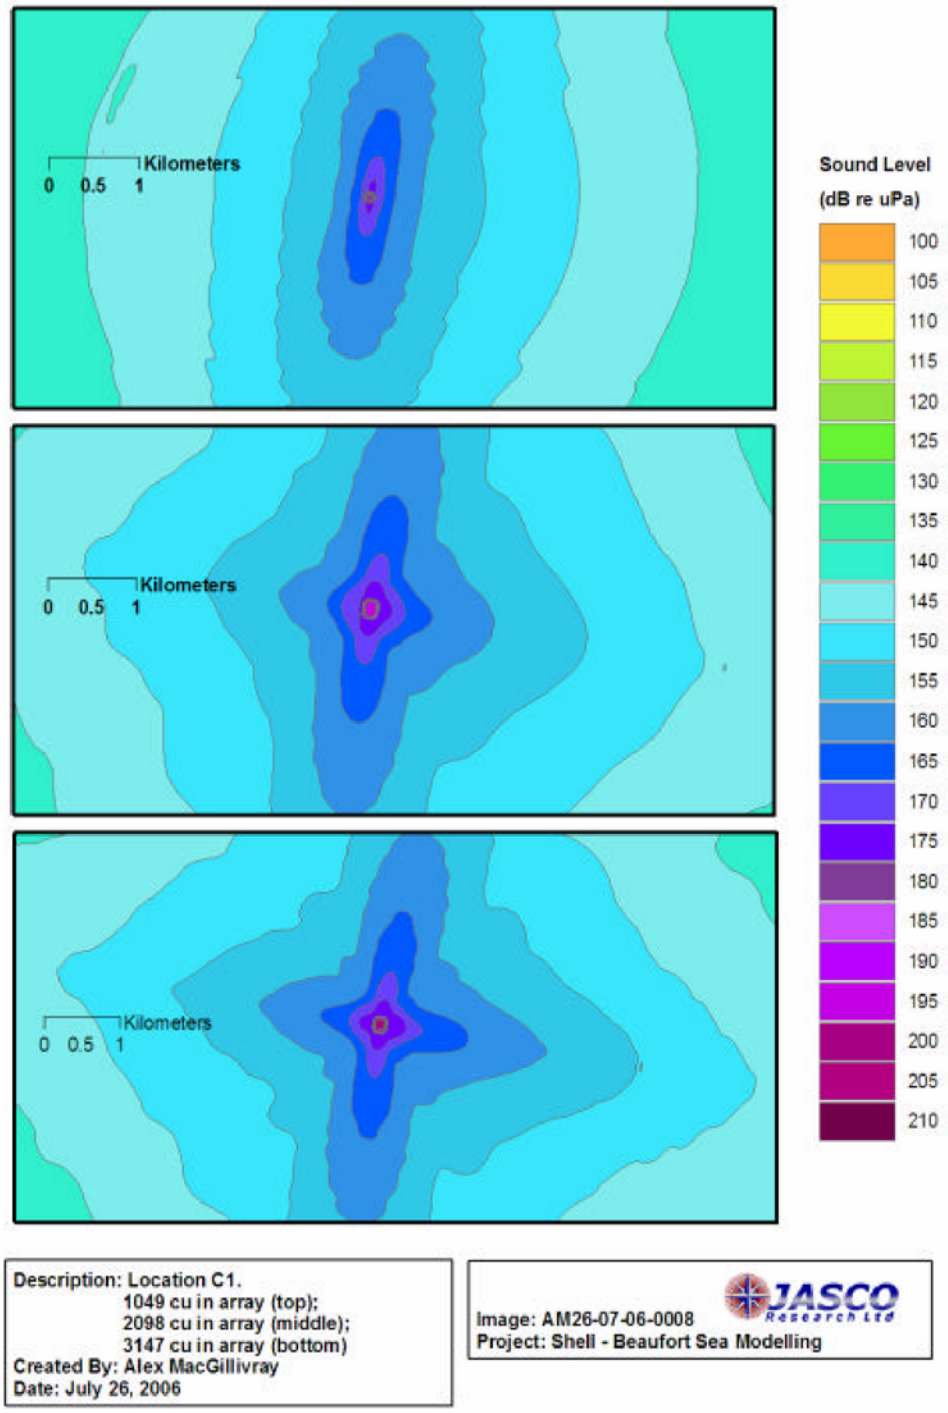

FIGURE 3.2. Maps of predicted received levels at 10 m depth, in SEL (energy) units, within several kilometers of a 1-string (top), 2-string (middle) and 3-string (bottom) airgun array being towed approximately East–West at source location C1.

these sources would be deployed at 1 m depth. The radii predicted for 90% rms levels, calculated using the Fourier synthesis technique, are presented in Table 3.4 (for the 20 in^3 source) and Table 3.5 (for the 10 in^3 source). Predicted radii both without and with frequency weighting, as described above, are shown. The predicted radii are small in part due to the small source, and in part due to the very shallow source depth (1 m). The latter would cause cancellation of a significant portion of the low frequency airgun energy through interactions between sound arriving via a direct-path and that arriving via a surface reflection path (surface ghost). Propagation modeling for these small sound sources was performed for two locations (B1 and B2) in the Beaufort Sea (Fig. 3.1).

240 in^3 Airgun Array

A small airgun array with total volume of 240 in^3 that could be used for shallow hazards surveying was also considered in the modeling. The array configuration consisted of two 2-gun clusters spaced 50 cm apart; each gun has a volume of 60 in^3. The radii predicted for the various 90% rms levels, without and with frequency-weighting, are presented in Table 3.6.

CONCLUSIONS

The acoustic environments at locations of the Beaufort and Chukchi Seas have been characterized by JASCO Research Ltd. (Austin et al. 2006b) and summarized in this chapter. The noise sources considered were three seismic airgun arrays with total volumes of 1049, 2098 and 3147 in^3 and several potential shallow hazards sources including individual airguns and a small airgun array. The acoustic output of each source was modeled and used as input to a state-of-the-art sound propagation model. This, in turn, was used to predict the acoustic energy levels that would be received as a function of distance and direction from these sources operating at representative locations in the Chukchi and Beaufort Seas. From these predictions of the received sound field in energy units, JASCO determined the distances at which received sound levels were expected to diminish below various levels that are of relevance for regulatory purposes, as measured on an rms basis (190, 180, … , 120 dB re 1 μPa rms). These predictions were expected to be considerably more accurate than could be achieved with simpler models that do not take account of site specific environmental conditions, such as sound velocity profile, water depth, and bottom and sub-bottom conditions. All of those factors are taken into account in JASCO's modeling, to the extent that these variables are known when modeling is done.

Species specific sensitivity weighting was applied to all of the model results to provide alternative safety radii that account for the relative sensitivity of different marine mammal groups to low-frequency sounds such as those that dominate seismic airgun sound. *M*-weighting curves were applied for "mid-frequency" cetaceans such as beluga whales, and for pinnipeds listening in water. These weighting functions reduced the predicted effective rms radii for airgun noise by a small amount for pinnipeds and by a larger amount for mid-frequency cetaceans. Although these reduced radii were not applied as safety radii or when calculating the number of mammals exposed to various sound levels during the project, the results indicate that the standard "unweighted" procedures used for pinnipeds and toothed whales during the project were protective in this respect.

Predicted distances for various sources and received levels are tabulated in this chapter. The maximum distances at which rms received levels of 190, 180, 160 and 120 dB re μPa were predicted to occur during operation of the 3147 in^3 airgun array in the Chukchi Sea were 0.23 km, 0.85 km, 5.7 km, and 42 km, respectively. The sound from the main airgun arrays was predicted to be ~5 dB stronger in the broadside direction than in the endfire direction. Comparisons of many of the predictions summarized in this chapter with empirical measurements from the Chukchi and Beaufort Seas can be found in Chapter 4.

4. ACOUSTIC MEASUREMENTS[5]

INTRODUCTION

During July through most of September 2006, Shell Offshore Inc. (SOI) conducted 3D seismic surveys in the Chukchi Sea. During August through early October SOI conducted shallow-hazards surveys in the Beaufort Sea. Both types of surveys relied on the generation of underwater acoustic pulses. Arrays of airguns towed behind a vessel were used for both the seismic and the shallow-hazards survey, and additional acoustic sources were used for the shallow-hazards survey. Greeneridge Sciences, Inc., measured the underwater sound levels produced by the vessels involved, including both seismic and support vessels, and by the acoustic equipment that was used, including airguns and the other shallow-hazards sources.

Shutdown or power-down radii are the ranges from a sound source within which the presence of a protected species requires suspension or alteration of operations because of the possibility of adverse effects, as defined in the applicable permits and authorizations. These mitigation criteria are commonly established to avoid or minimize the possibility of hearing damage. They may also be designed to reduce behavioral disturbance. For airguns, the government-mandated shutdown or power-down radii used in this project were the maximum distances within which received levels of the pulsed sounds could exceed 190 dB re 1 μPa SPL[6] (for pinnipeds) or 180 dB re 1 μPa SPL (for cetaceans). In certain situations, mitigation would also be required when cetaceans were found within the 160 or 120 dB re 1 μPa SPL radii.

Before the onset of field work, JASCO Research Ltd. had estimated, by numerical modeling, the distances from the airgun arrays at which the broadband (rms) received levels would be 190 dB, 180 dB, 170 dB, 160 dB, and 120 dB re 1 μPa (see Chapter 3). Early in the respective periods of operation of the seismic and shallow-hazards vessels, Greeneridge Sciences measured the actual underwater sounds from these sources to establish appropriate mitigation radii for the seismic and shallow-hazards survey equipment. Measured values were used to recommend mitigation radii for use by marine mammal observers on the seismic ships during data acquisition and subsequent data analyses, and these empirically-determined values were compared to the values that had been predicted by modeling.

This chapter reports on data collected during two separate field trips involving three different vessels. The seismic ship *MV Gilavar* and the chase vessel *MV Jim Kilabuk* were used in the Chukchi Sea for seismic data acquisition, and the tug and shallow-hazards survey vessel *MV Henry Christoffersen* (or *Henry C.*) was used in the Beaufort Sea for acquisition of shallow-hazards data.

Objectives

Field objectives were similar in the Chukchi and Beaufort seas and included three components:

- Field measurements of the sounds produced by airguns (*Gilavar* and *Henry Christoffersen*) or sources used in shallow-hazards surveys (only *Henry C.*). These measurements were to be made at the beginning of the seismic surveys in each region, and the collected data were to be analyzed immediately to the extent necessary to establish the mitigation radii. Ranges at which broadband levels were received at 190, 180, 170, 160, and 120 dB (SPL) re 1 μPa were to be determined and reported within 72 hours to Shell.

---

[5] By Susanna B. Blackwell, Robert G. Norman, Charles R. Greene Jr. (Greeneridge Sciences Inc.), and W. John Richardson (LGL).

[6] SPL: sound pressure level, i.e., root mean square (rms) pressure level averaged over duration of sound pulse.

- After the field season, the empirical data were to be further analyzed to obtain a more comprehensive assessment of pulse characteristics—including duration, peak level, and SEL (sound exposure level) as well as SPL (=rms)—as a function of range and aspect. Spectral properties of the pulses, in particular one-third octave band characteristics, were also to be documented.
- Field measurements of radiated propulsion sounds as a function of distance from all vessels involved: the seismic vessel *Gilavar* and the support/supply/chase vessel *Jim Kilabuk* in the Chukchi Sea, and the shallow-hazards survey vessel *Henry C.* in the Beaufort Sea.

Measurements were obtained in July (Chukchi Sea) and August (Beaufort Sea) 2006 and the results are presented in this report. Field reports including recommended mitigation radii were submitted to Shell on 26 July and 10 August 2006, respectively, for measurements in the Chukchi and Beaufort seas. The final versions of these field reports are appended to this chapter as Annexes 4.1 and 4.2.

METHODS

Equipment

Recordings were made using two Autonomous Seafloor Acoustic Recorders model B (ASAR-B). A picture and schematic representation of an ASAR-B are shown in Figure 4.1. The ASAR-B consists of a pressure housing containing the recording electronics and a rechargeable gel cell battery. The recorder includes a two-channel signal digitizer with 16-bit quantization. It was initially programmed to sample at 44.1 kHz on each channel, providing a useable frequency range of 5 to 20,000 Hz. One of the ASAR-Bs in the Beaufort Sea measurements was re-programmed to sample at 192 kHz, because of the presence of higher frequency sound sources (see below). Data were written to an 8 GB solid state memory (Flash card), providing ~13 hours of continuous recording at the 44.1 kHz sampling rate. For deployment on the sea floor the ASAR-B housing was mounted in the center of a pyramidal steel frame weighing ~41 kg (~90 lbs, Fig. 4.1). Hereafter ASAR-Bs will be referred to simply as ASARs.

Two different types of hydrophones were used concurrently, one on each recording channel:

- A calibrated ITC model 8212 broadband hydrophone with a low-noise preamplifier: This was the more sensitive of the two hydrophone types, best suited for recording sound levels below ~135 dB re 1 μPa (this type of hydrophone saturated at peak levels of about 145 dB re 1 μPa 0-peak).
- A calibrated ITC model 1032 spherical broadband hydrophone without preamplifier: This hydrophone was included to permit undistorted recordings of high-level sound pulses. This type of hydrophone saturated at peak levels close to 207 dB re 1 μPa 0-peak.

The hydrophone cables were threaded through the top of the pyramidal frame and the hydrophones were buoyed up from the sea floor by a glass sphere (Fig. 4.1A). When deployed, the two hydrophones were ~3.5 m (1032) and ~2 m (8212) off the sea floor. The hydrophone cables were faired to minimize strumming (see Fig. 4.1B).

All hydrophones had been calibrated before the onset of the field season at the ITC calibration facility in Goleta, California, which employs standards traceable to the National Standards for underwater sound measurements. The ITC 8212 hydrophones were recalibrated on 9 November 2006. Thorough calibration of the hydrophones and recording equipment allowed all results to be referred to the standard acoustic

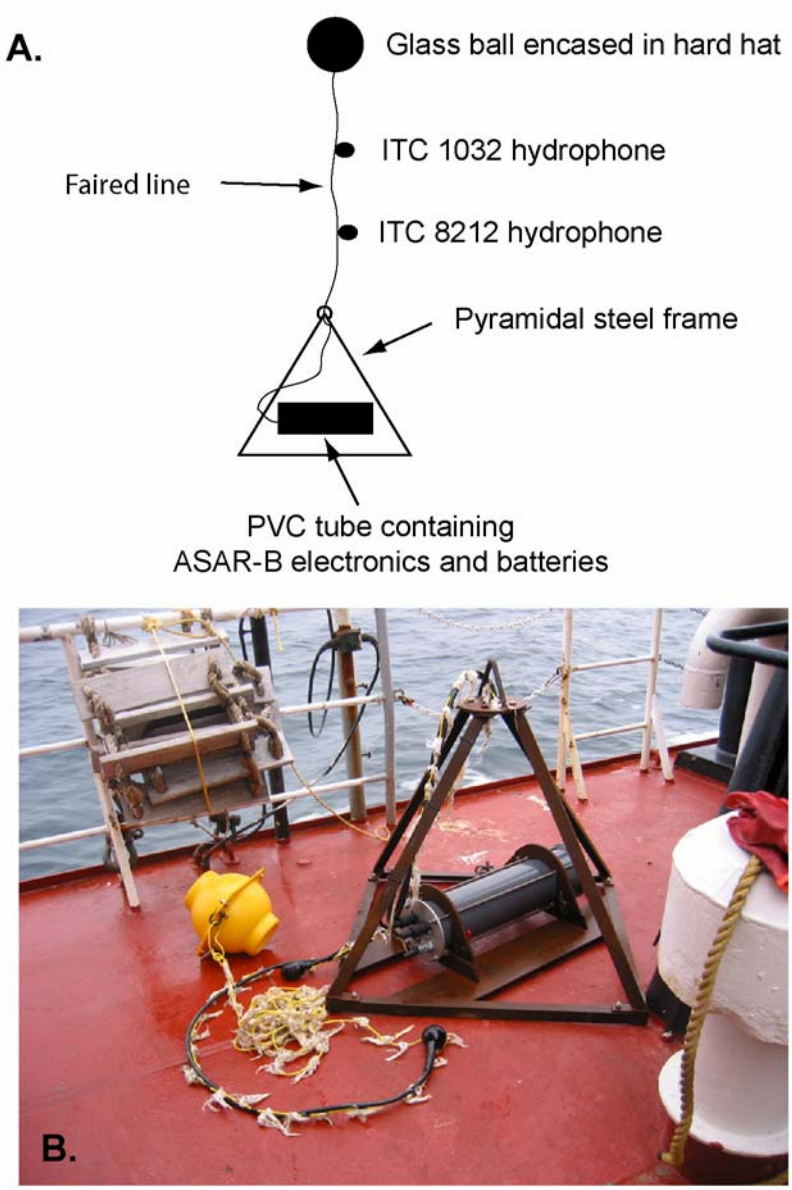

FIGURE 4.1. ASAR-B recorder. ***(A)*** Schematic diagram of the components of the ASAR-B recorder as deployed on the sea floor. Not drawn to scale. ***(B)*** An ASAR-B on the deck of the M/V *Kilabuk* after retrieval. The hydrophones are the black spheres on the cable in the foreground. The yellow sphere to the left of the frame is the hard hat containing the glass ball.

pressure of one micropascal (1 μPa). Both hydrophone types therefore had calibrated responses for the frequency range 5–30,000 Hz, and the ITC 1032 hydrophones were calibrated to 50 kHz.

A Seabird model 19Plus CTD (conductivity-temperature-depth) probe was used at each recording site to obtain a sound velocity profile.

Deployment Procedure

Both ASARs were used in each recording session. The basic layout was the same during measurements of vessel sounds and airgun / shallow-hazards survey sounds and is shown in Figure 4.2. In

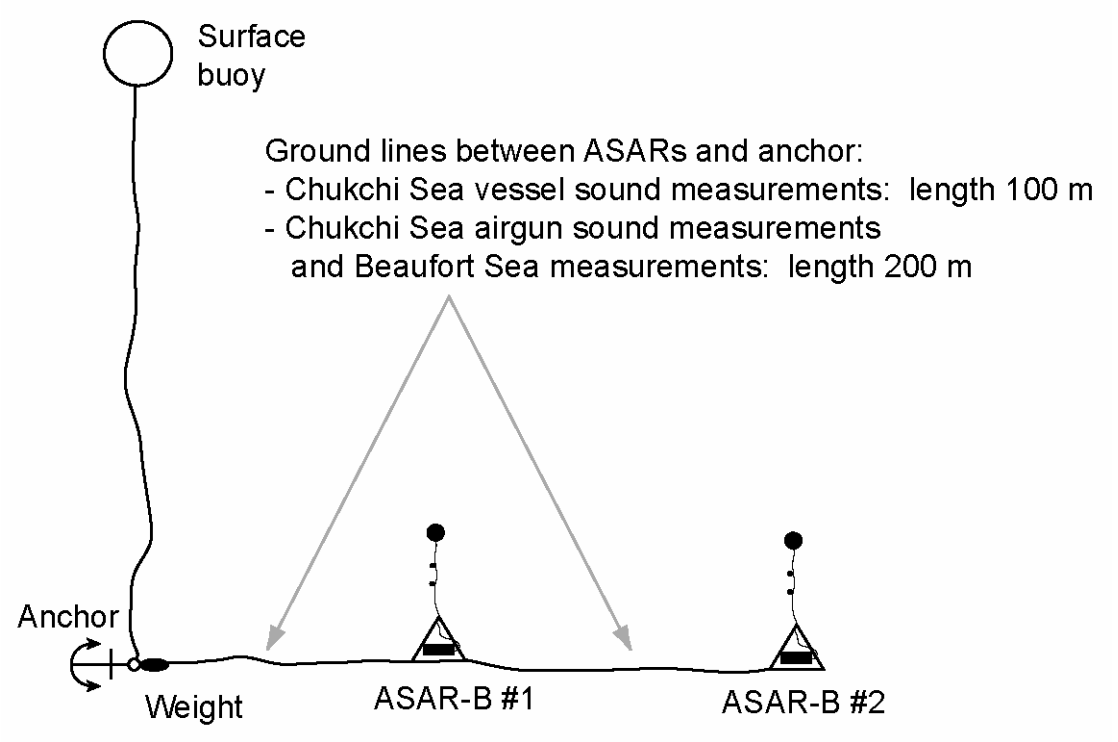

FIGURE 4.2. Deployment layout for ASAR-B recorders. A small weighted anchor is attached to a surface buoy to facilitate retrieval. A ground line connects the anchor to the first ASAR-B, itself connected by a ground line to the second ASAR-B. Anchor and recorders are laid out in a line on the seafloor.

the Chukchi Sea, deployments were done from the *Kilabuk*'s FRC (Fast Rescue Craft) with a crew of four people (boat driver, scientist, and two deck hands). In the Beaufort Sea, deployments were done directly from the deck of the *Henry C.* At the desired deployment location, the anchor and weight were lowered to the bottom with a line connecting them to a surface buoy. A GPS waypoint[7] for the location was obtained. A ground line connecting the anchor to the first ASAR was laid out in a straight line. The length of this line, and of the line between the two ASARs, was 200 m except in the Chukchi vessel sound measurements in which it was 100 m (Fig. 4.2). When the end of the ground line was reached, a "lowering line" was threaded through the "hoop" at the apex of the ASAR's pyramidal cage and the recorder was lowered to the sea floor. A GPS waypoint was obtained at the recorder location. The second length of ground line and the second recorder were deployed in similar fashion.

Deployments in the Chukchi Sea were made on 12 July to record vessel sounds of the *Kilabuk* and *Gilavar*, and on 21 July to record airgun sounds. In the Beaufort Sea the airgun and vessel sound recordings (*Henry C.*) were done concurrently during a single deployment of the ASARs on 8 August. Table 4.1 summarizes information pertaining to these deployments.

[7] A Garmin GPS model 12CX was used during the Chukchi Sea measurements. Deployment positions in the Beaufort Sea were recorded directly by the GPS on the *Henry Christoffersen*.

TABLE 4.1. Deployment dates, deployment locations (WGS84) and water depth for ASARs during recordings of vessel and airgun sounds.

Water depth (m)	52	42	48

Recording Procedure

After the ASARs were deployed the sound source — airguns (see specifics below) or vessel — was operated over a dedicated test course referenced to the ASAR positions. There were two main types of recording legs:

- endfire aspect with the sound source opening (stern aspect) or closing (bow aspect) range from the ASARs. In the Chukchi Sea measurements, the test course included travel directly over ASAR #2, but not ASAR #1. Therefore, strictly-endfire data were only available from ASAR #2, even though at farther distances ASAR #1 was at very close to endfire aspect, and the data recorded by both ASARs were identical. For the endfire aspect, measurements were obtained to ~10 km distance for vessel sound measurements in the Chukchi Sea, ~30 km for airgun sound measurements in the Chukchi Sea, and ~20 km for the Beaufort Sea measurements.
- crossfire aspect (broadside aspect) with the sound source passing laterally at several closest points of approach (e.g., 100 m, 500 m, 1000 m) from the recorders. We restricted broadside data to those collected while the sound source was within ±5° of broadside, i.e., within an ~10° span of angles (Fig. 4.3).

During all recordings, the time and GPS position of the sound source were logged every 4–20 sec, depending on the type of measurements:

- The Chief Positioning Specialist on the *Gilavar* provided source positions. During measurements of vessel sounds, the position of the *Gilavar*'s stern was logged every 10 sec. During measurements of airgun sounds the position of the geometric center of the airgun array was logged at every shot, which took place every 19–20 sec.
- During measurements of the *Kilabuk*'s vessel sounds, a handheld GPS receiver (Garmin GPS model 12CX) logged the *Kilabuk's* position every 16 sec.
- On the *Henry C.*, position information was provided by the Geo LLC navigator for every shot of the airgun cluster, about every 4 sec.

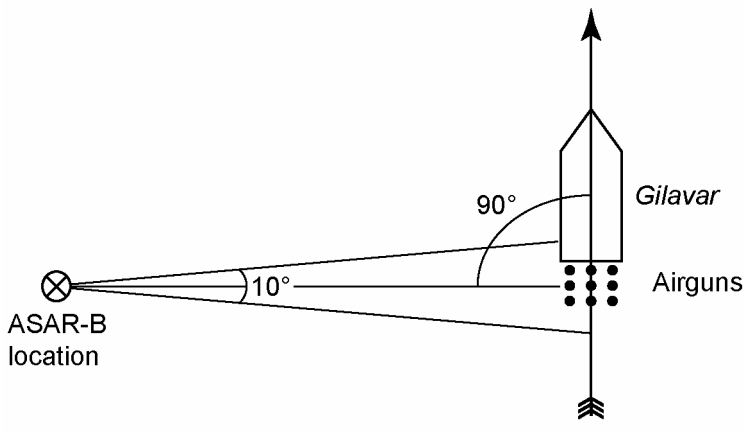

FIGURE 4.3. Circumstances in which data were included in the broadside category (see text).

Sound Sources

The ***Gilavar*** is a seismic research vessel, 84.9 m (279 feet) in length. It has five diesel electric engines, of which four are Bergen KRGB-9 units (2067 brake horse power or BHP each) and one is a Caterpillar 3516B (1855 BHP), for a total of 10,123 BHP. During the Chukchi Sea measurements, the *Gilavar* used two airgun array configurations:

- A three-string array with a total volume of 3147 in^3, with eight airguns per string (i.e., 24 guns total)
- A one-string array with a total volume of 1049 in^3, comprised of eight airguns.

Source depth was 6 m and firing interval was ~19 sec (50 m). Recordings were made using both array configurations consecutively. Although hydrophone streamers are deployed during production operations, they were not deployed during the sound source verification recordings.

The ***Jim Kilabuk*** is an icebreaking tug and supply vessel, 62.5 m (205 feet) in length. It has two turbo-charged diesel engines, for a total of 7200 brake horse power (BHP). The *Kilabuk* was previously (in the 1980s) named the *Canmar Supplier IV*.

The ***Henry Christoffersen*** is a pusher-towing tug, 56.4 m (185 feet) in length. The *Henry C.* has four engines at 1125 HP each for a total of 4500 BHP. The *Henry C.* used five different sound sources for shallow-hazards surveys. These included the following:

- An airgun cluster consisting of four 70 in^3 airguns in a tuned array cluster (total volume 280 in^3), at source depth 2.5 m, with firing interval of ~4 sec (6.25 m)
- A Seabat 8101 bottom mapping sonar operating at 240 kHz
- An SIS 1500 seafloor-imaging sonar operating at 190 kHz
- A chirp sonar (sub-bottom profiler) operating at 2–7 and 8–23 kHz, transducer depth ~1 m, 0.25–5 sec interval
- A bubble pulser operating at frequencies near 400 Hz, 0.5–5 sec interval

The airgun cluster was expected to be the strongest of these sound sources. Since the operational frequencies of the bubble pulser overlapped with those for the airguns, different pulse intervals for the two sources were used: 8 s for the airguns and 6 s for the bubble pulser. The Seabat 8101 bottom mapping

sonar and the SIS 1500 seafloor-imaging sonar both operate at frequencies >180 kHz. That is the highest frequency considered to be of possible influence to any species of marine mammal, including mid- and high-frequency specialists such as toothed whales (Odontocetes) (Miller et al. 2005). No measurements of sounds from these two high-frequency sources were planned since there should be no exclusion zones for seals or whales during their operation.

Retrieval Procedure

When recordings of sound-producing activities were complete, the ASARs were retrieved. In the Chukchi Sea, this was done using the *Kilabuk*'s FRC and a crew of five people (boat driver, scientist, and three deck hands). The surface buoy was retrieved first, followed by the anchor and weight, ASAR #1, and lastly ASAR #2 (see Fig. 4.2). All gear was hauled in by hand. On the *Henry C.*, the gear was hauled in from the port side of the vessel, with help from the vessel's main winch.

Data Analysis

Recorded data were saved as a series of 422.1 MB files which were transferred from the Flash card to laptop computers running MATLAB and custom analysis software. They were then calibrated in units of sound pressure over the data bandwidth (5–20,000 Hz or 5–90,000 Hz depending on sampling rate).

Broadband Analysis

For ***vessel sound measurements*** the data were partitioned into non-overlapping segments of 1 sec each and a broadband (10–20,000 Hz) sound pressure level was obtained for each 1-s segment.

For ***airgun sound measurements*** the sound pressure time series (see Fig. 4.5, later) was used for selecting samples for analysis. Four parameters were determined for each selected pulse (see McCauley et al. 1998, 2000a,b; Burgess and Greene 1999):

- **peak pressure**, i.e. the instantaneous maximum of the absolute sound pressure, in dB re 1 μPa;
- pulse **duration**, defined as the time interval between the arrival of 5% and 95% of the total pulse energy;
- pulse **sound pressure level** (SPL), squared pressure averaged over the pulse duration, in dB re 1 μPa;
- pulse **sound exposure level** (SEL), defined as the squared instantaneous sound pressure integrated over the pulse duration, in dB re 1 $\mu Pa^2 \cdot s$. This measure is related to the total physical energy conveyed in each pulse, and was calculated excluding the contributions of background sound as characterized by measurements between pulses.

SPL and pulse duration are highly interdependent. For example, low-level reverberation that extends the pulse length can result in a longer averaging time and thus a lower SPL. The SEL is not influenced by the duration, as it is a measure of the total energy in the pulse regardless of the pulse duration.

One of two propagation models was fitted by the least squares method to broadband levels of vessel sounds, or to the peak, SPL, and SEL values for seismic pulses, in order to characterize propagation loss underwater. These models were based on logarithmic spreading loss:

$$\text{Received Level } (\mathbf{RL}) = A + B \cdot \log(R) \quad (1)$$

$$\text{Received Level } (\mathbf{RL}) = A + B \cdot \log(R) + C \cdot R \quad (2)$$

In these equations, R is the range to the source in m and the units for **RL** are dB re 1 μPa or 1 $\mu Pa^2 \cdot s$. The constant term (A) is the hypothetical level 1 m from the source, extrapolated back to 1 m range based on far-field measurements. This hypothetical value would equal the actual level at 1 m only if the source were a point source and if loss rates were consistent at all distances from 1 m to the maximum measurement distance, neither of which is the case. The estimated A value is useful mainly as a basis for comparison with other sources operating in the same region. The spreading loss term (B), which is negative, varies with the dominant frequency in the pulse, water depth, bottom topography, and bottom composition. C (in dB/m) is the coefficient describing losses due to scattering and absorption; like B it is negative. The composition and topography of the seabed and sea surface roughness will affect such losses.

The choice of one model over the other is generally determined by the range and water depth over which the measurements were made. In our measurements, water depths were all similar, so our choice was determined by range. When the maximum measurement distance was less than ~10 km, Eq. (1) was used. When measurements extended to greater distances, as for most of the airgun sound measurements, the $C \cdot R$ term was expected to become significant, and Eq. (2) was used. C is a small number except in very shallow water and therefore its effect is difficult to measure until R becomes large.

Spectral Analysis

The spectral composition of each vessel's sound and of the airgun pulses was obtained from data recorded at short ranges (at or close to the CPA). Spectral processing yielded both one-third octave band levels and sound spectral density levels. The one-third octave band levels represent the amount of sound in parts of the frequency spectrum (bands) whose lower and upper frequencies differ by a factor of 1.26×. Spectral density levels represent the amount of sound in 1-Hz bands and are expressed in dB re 1 $\mu Pa^2/Hz$.

M-weighting

Hearing abilities differ among different types of marine mammals, with some marine mammals being more sensitive to low frequencies (e.g., baleen whales) while others are more sensitive to high frequencies (e.g., porpoises). In assessing the effects of sound on different types of marine mammals it is useful to weight the sounds reaching the animal by de-emphasizing frequencies which the animal of concern cannot hear, or hears only weakly. Ideally there should be a specific weighting function for each species of marine mammal, but audiograms are not available for most species. In the interim, all marine mammal species have been placed into one of five groups, based on their hearing function (Miller et al. 2005; Southall et al., submitted). These five groups are low-, mid-, and high-frequency cetaceans, pinnipeds in water, and pinnipeds in air. Three of these groups are of interest in this report: mid-frequency cetaceans (including beluga whales), pinnipeds in water (seals and walruses), and low-frequency cetaceans (bowhead and gray whales). The different M-weighting functions are determined by the variables f_{low} and f_{high}, which are conservative estimates of the lower and upper boundaries of effective hearing for each group:

- mid-frequency cetaceans: f_{low} = 150 Hz, f_{high} = 160 kHz;
- pinnipeds in water: f_{low} = 75 Hz, f_{high} = 75 kHz;
- low-frequency cetaceans: f_{low} = 7 Hz, f_{high} = 22 kHz;

The M-weighting functions have been defined primarily for applications involving exposure to strong sounds, including pulsed sounds (Miller et al. 2005; Southall et al., submitted). These functions are analogous to the C-weighting function that is widely used in characterizing effective levels of strong pulsed sounds insofar as they affect humans. Annex 4.3 shows the M-weighting functions in relation to frequency.

To assess the effect of *M*-weighting on broadband SPLs and SELs, a subset of seismic pulses was analyzed after being weighted according to the three types of *M*-weighting functions described above.

RESULTS

Seismic and Sonar Sound Measurements

Broadband Levels for Seismic Vessel Gilavar *(Chukchi Sea)*

On 21 July 2006 both ASARs were deployed in the locations given in Table 4.1. To maximize recording time, the ASAR start times were offset by 6 h (11:00 for ASAR #2 and 17:00 for ASAR #1). The *Gilavar* followed a predetermined course over and away from the ASAR locations, to provide recordings of airgun sounds from different distances and different aspects (bow, stern, broadside). The *Gilavar*'s course is shown in Figure 4.4. During these recordings the *Gilavar* traveled at a speed of ~5.5 knots (10.2 km/h or 6.3 mph).

Sound pressure time series of airgun sounds (three-string array), as recorded by ASAR #2 (hydrophone ITC 1032), are shown in Figure 4.5. Data recorded with the more sensitive hydrophone (model ITC 8212) were saturated for most of the obtained pulses, so we only present data obtained with the less sensitive hydrophone.

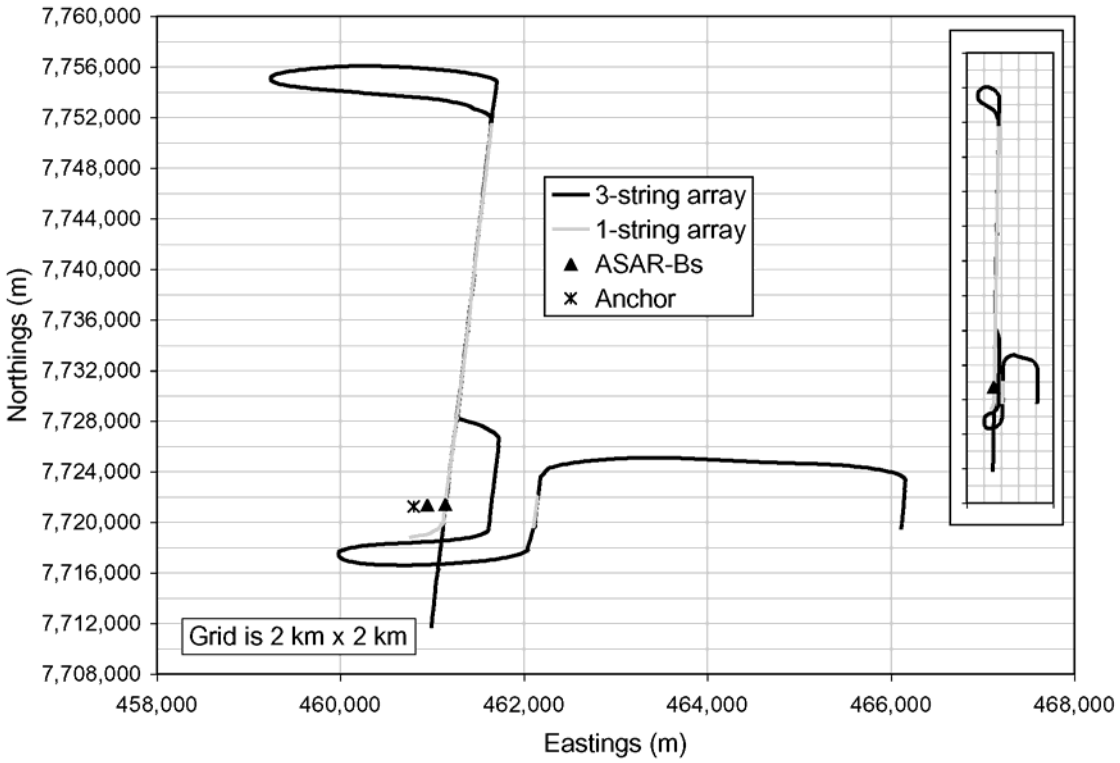

FIGURE 4.4. Track of the M/V *Gilavar* during airgun sound measurements, while towing a three-string airgun array (black) and a one-string array (gray), 21 July 2006, Chukchi Sea. The grid squares are 2 km × 2 km; the main map has been extended in the E–W direction to better show the ship track but the inset map shows the track to scale. Filled triangles show the ASAR locations.

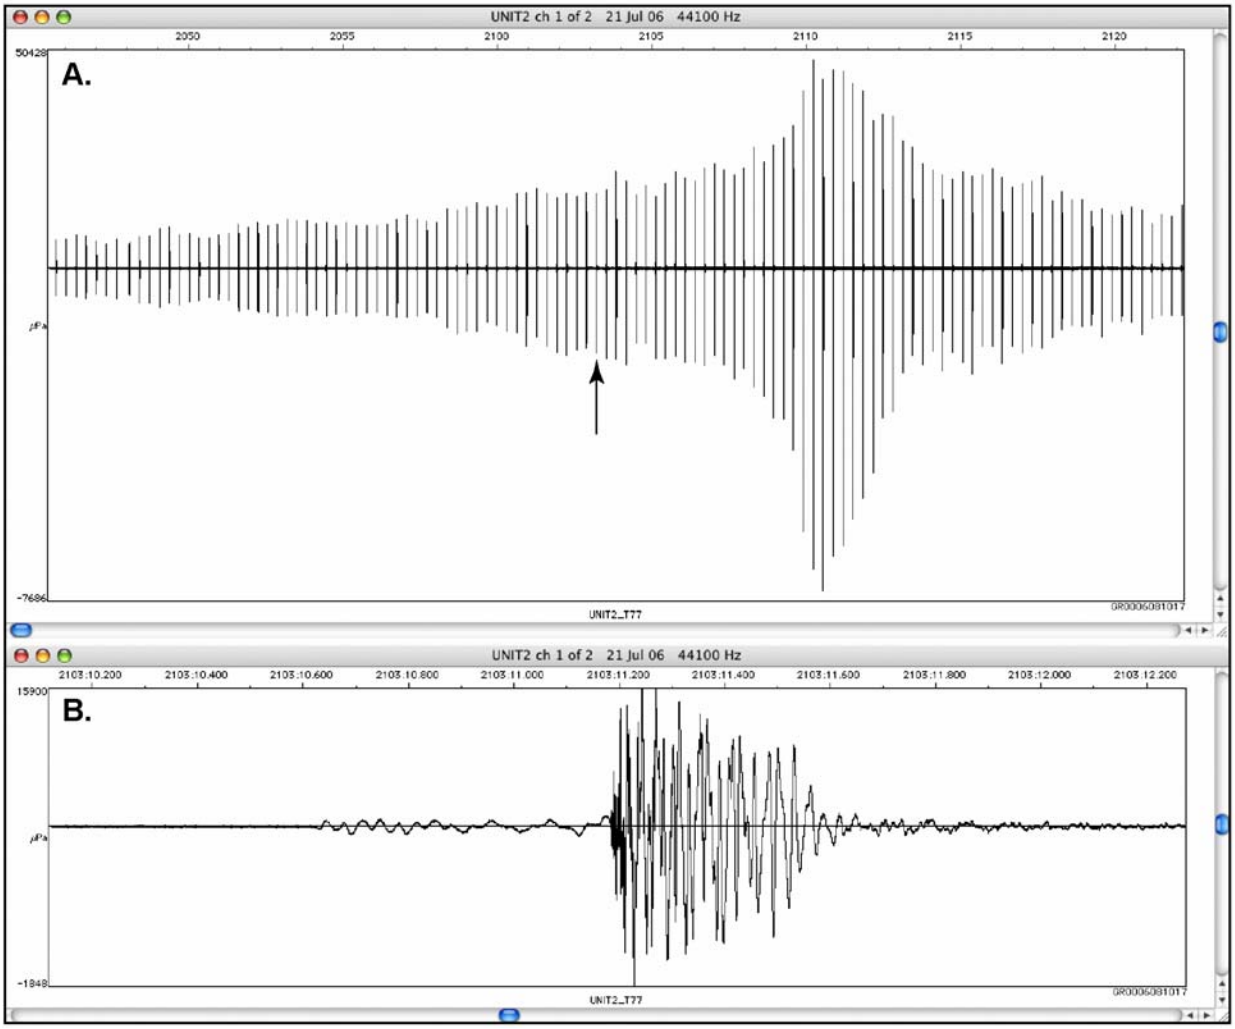

FIGURE 4.5. Sound pressure time series (SPTS) of airgun sounds as recorded on 21 July 2006 by ASAR #2, ITC 1032 hydrophone. ***(A)*** About 37 min of recording while the *Gilavar* passed by ASAR #2 at a distance of 1 km. Calculated distance from ASAR #2 to the center of the airgun array was 3880 m at the time of the first pulse shown, 1008 m at the CPA, and 2007 m at the time of the last pulse shown. ***(B)*** Detail of pulse shown by arrow in plot (A).

Three-String Array Configuration (3147 in^3).—Broadband levels of airgun sounds for the three-string array configuration are shown in Figures 4.6–4.9. Figure 4.6 shows bow aspect data for four pulse parameters as a function of distance from the airguns: peak level, SPL, SEL, and pulse duration. For peak, SPL, and SEL values Eq. (2) was fitted to the data. The resulting equations and correlation coefficients (R or r, as appropriate) are shown in Table 4.2.

Figures 4.7 and 4.8 show the same types of data as Figure 4.6, but for the stern and broadside aspects. Broadside data were only collected to a distance of ~5 km. Therefore Eq. (1) was fitted to the data, instead of the more complex model [Eq. (2)] which takes scattering and absorption losses into account but requires measurements over a larger span of distances.

Propagation effects, such as geometric dispersion, predictably lengthen pulse durations with increasing distance from the sound source (see Greene and Burgess 2000). This can be seen in Figures 4.6–4.8 for all three aspects.

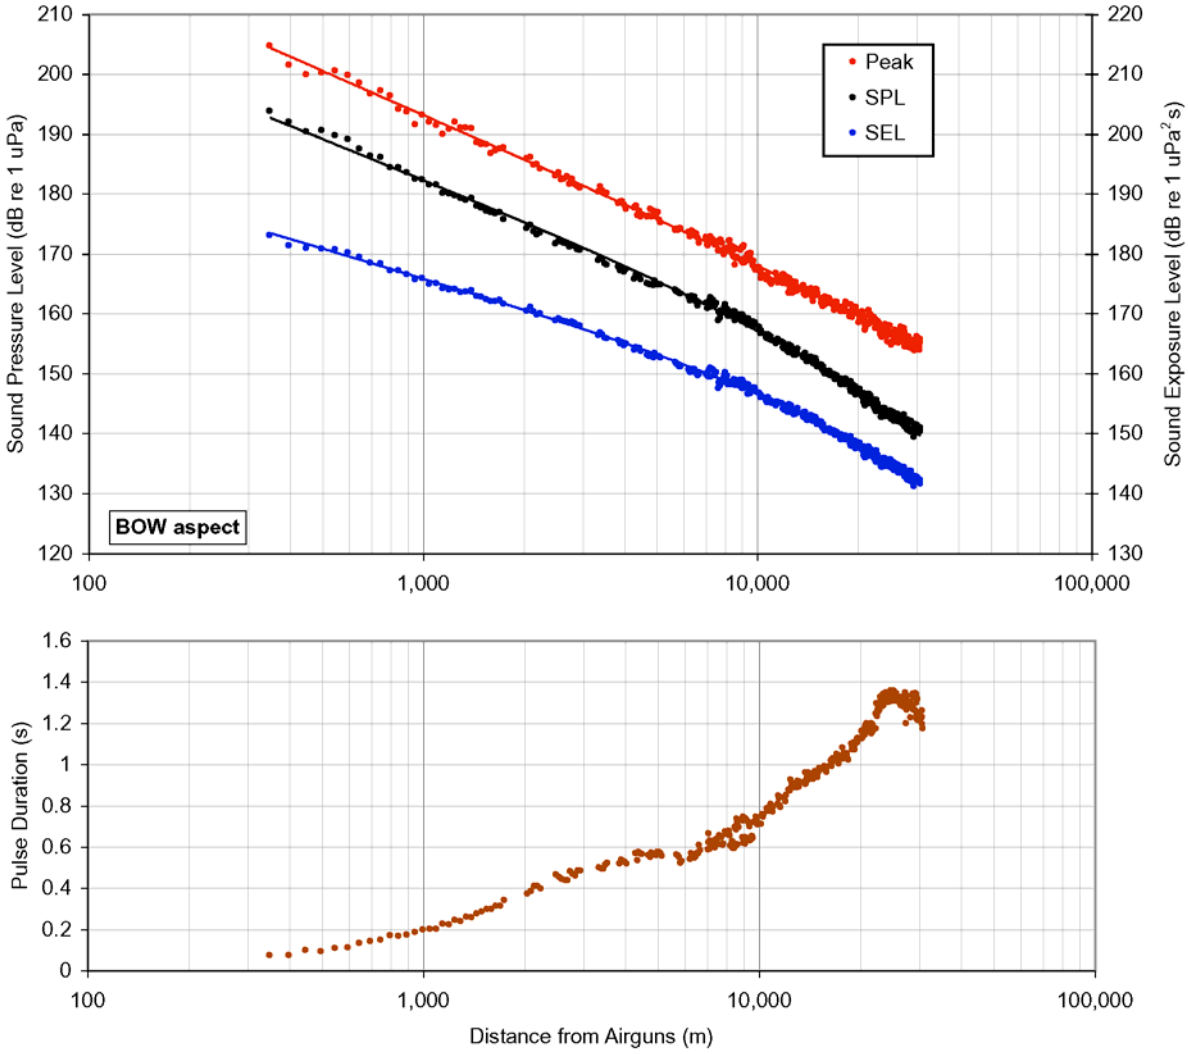

FIGURE 4.6. Received broadband levels of sound with *Gilavar*'s three-string array (3147 in^3) for **bow** aspect, as a function of distance from the airguns, 21 July 2006, Chukchi Sea. The top plot shows peak levels and SPLs, with values to be read on the left y-axis (dB re 1 μPa), and SELs with values to be read on the right y-axis (dB re 1 $\mu Pa^2 \cdot s$). Note that to avoid overlap, values on the two y-axes are offset by 10 dB. Equations for the regressions are given in Table 4.2. The bottom plot shows pulse duration as a function of distance from the airguns.

Figure 4.9 compares the fitted regression lines from Figures 4.6–4.8 in order to illustrate the effect of aspect (bow, stern, and broadside). For bow and stern aspects, the SPL and SEL regressions have been extrapolated beyond the maximum distances of our measurements to the range where the received level has diminished to 120 dB. These extrapolations are for purposes of comparison only, due to uncertainties in the propagation model and the effects of measurement variability on the regressions. However, for SEL, the consistency of the results for the 3 aspects suggests that—for this acoustic measure—measurement variability was small. Figure 4.9 shows that, for the *Gilavar*'s 3-string array, aspect dependence was relatively small, at least out to the maximum distance (5 km) at which broadside-aspect data were acquired.

TABLE 4.2. Values for variables *A*, *B*, and *C* [Eq. (1) and (2)] in the regressions shown in Figures 4.6–4.9; data were collected using the three-string airgun array in the Chukchi Sea. Values are shown for peak level, sound pressure level (SPL), and sound exposure level (SEL) for all three aspects (bow, stern, broadside). The multiple-*R* or *r*-value is also shown for each equation, as well as the range of distances over which the measurements were made and the sample size (number of pulses analyzed).

	A	*B*	*C*	*R* (or *r*)	Range of distances (km)	Sample size
BOW					0.35–30.6	391
Peak	266.4	–24.34	$-9.45\ 10^{-5}$	–0.997		
SPL	249.5	–22.26	$-3.25\ 10^{-4}$	–0.998		
SEL	224.6	–16.11	$-3.54\ 10^{-4}$	–0.998		
STERN					0.30–33.9	232
Peak	249.8	–19.90	$-2.24\ 10^{-4}$	–0.997		
SPL	247.2	–22.40	$-2.05\ 10^{-4}$	–0.997		
SEL	221.0	–15.44	$-3.55\ 10^{-4}$	–0.998		
BROADSIDE					0.52–5.16	54
Peak	253.5	–19.71	N.A.	(–0.986)		
SPL	239.7	–18.96	N.A.	(–0.994)		
SEL	222.9	–15.41	N.A.	(–0.994)		

One-String Array Configuration (1049 in^3).—Broadband levels of airgun sounds for the one-string array configuration are shown in Figures 4.10–4.12. Figure 4.10 shows stern aspect data for peak level, SPL, SEL and pulse duration, as a function of distance from the airguns. For all sound level parameters Eq. (2) was fitted to the data. The resulting equations and multiple-R values are shown in Table 4.3. The equivalent bow and broadside data are shown in Figure 4.11. Bow and broadside data were only collected to a distance of less than 2 km; therefore Eq. (1) was fitted to the data. The resulting equations and *r*-values are shown in Table 4.3.

Figure 4.12 compares the fitted regressions lines from Figures 4.10 and 4.11 in order to illustrate the effect of aspect. For the stern aspect, the regression has been extrapolated beyond the maximum distance of our measurements to the distance where the received level was 120 dB. (Data for bow and broadside aspects were not collected over a large enough range to justify extrapolation.) As predicted by the pre-field-season modeling (Chapter 3), aspect dependence was more marked for data collected with the one-string array, compared to the three-string array (*cf.* Fig. 4.9).

Relationship Between SPL, SEL, and Range.—Figure 4.13 summarizes the relationship between SPL, SEL, and the distance from the hydrophone to the airguns. The difference between SPL and SEL is mathematically related to pulse duration and is shown in Fig. 4.13A (i.e., if the actual data were plotted they would fall on the shown line and *r* would equal 1.0). Since we define pulse duration as the time interval between the arrival of 5% and 95% of the total pulse energy (see Methods section), SPL and SEL are equal (i.e., their difference is 0) when pulse duration = 0.9 sec. When x = 0.9, y = – 0.4576 – 10·log(0.9) = 0, as

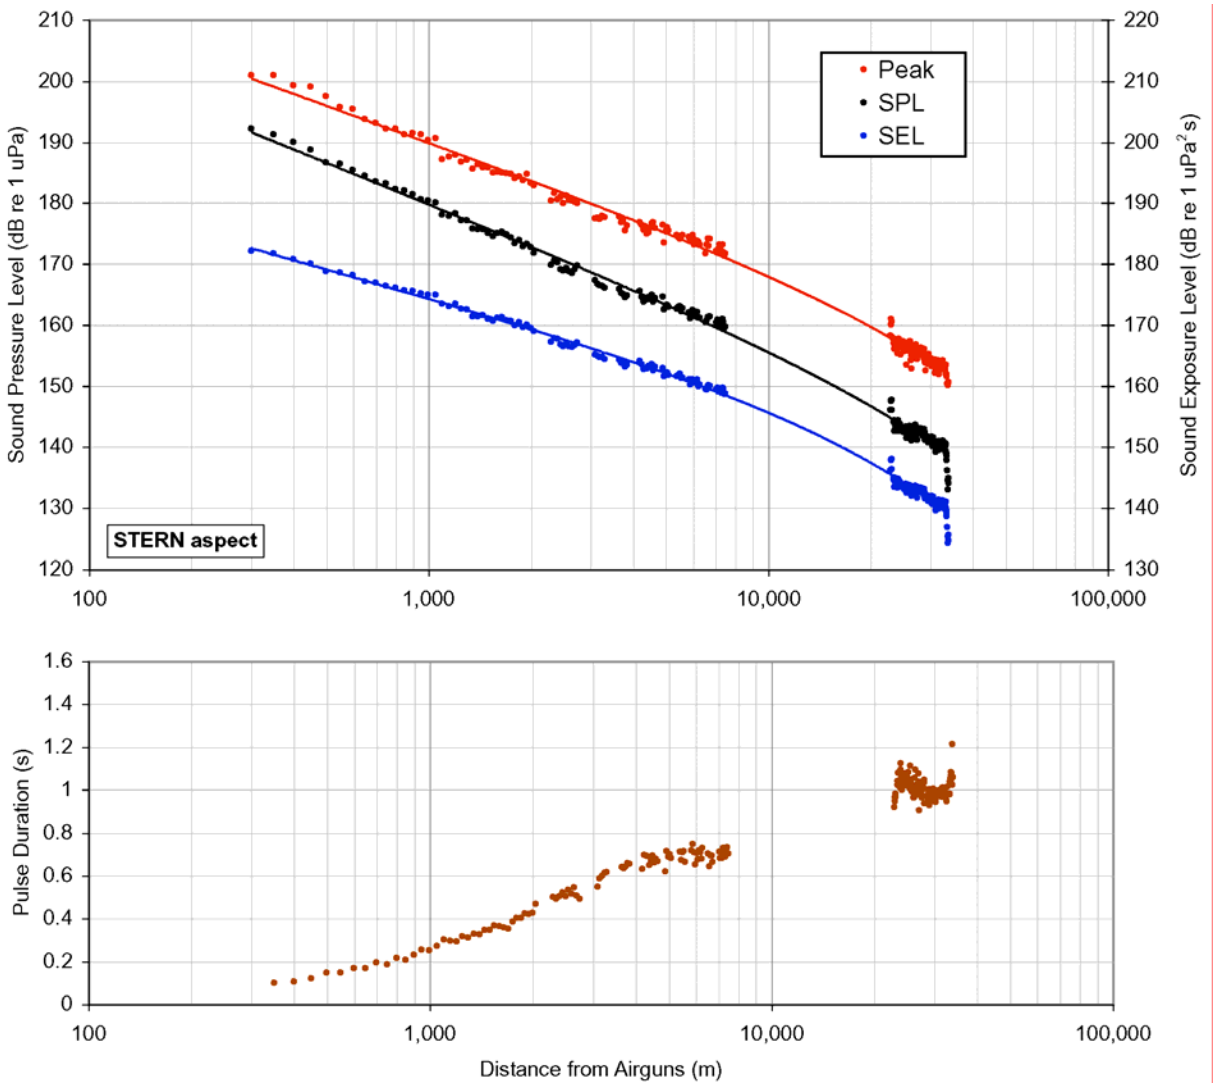

FIGURE 4.7. Received broadband levels of sound with *Gilavar*'s three-string array (3147 in^3) for **stern** aspect, as a function of distance from the airguns, 21 July 2006, Chukchi Sea. Plotted as in Figure 4.6.

10·log(0.9) = –0.4576 (see Fig. 4.13A). Figures 4.13B and C illustrate how the difference between SPL and SEL changes with distance from the airguns for data collected with the three- and one-string arrays, respectively. The difference between SPL and SEL values was highest closest to the sound source, with SPLs about 10 dB higher than SELs ~300 m from the airguns. Out to ~3 km the difference between SPL and SEL decreased by about 8.5 dB / tenfold change in distance. Beyond 10–16 km the difference becomes negative, i.e., SEL values are larger than SPL values. This reflects the fact that most pulse durations had been "stretched" by propagation phenomena to 1 sec or greater at distances beyond 10–16 km (Fig. 4.6, 4.7, 4.10).

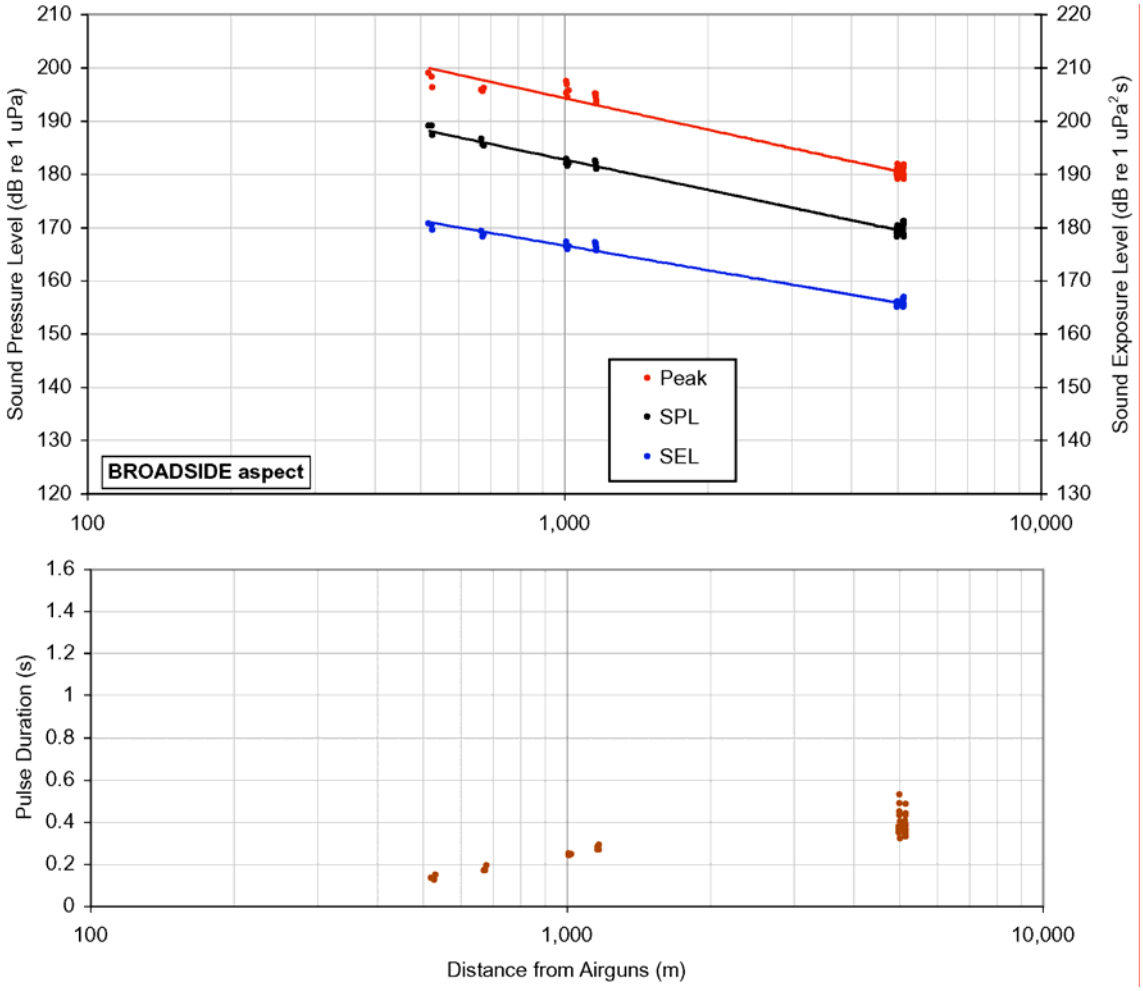

FIGURE 4.8. Received broadband levels of sound with *Gilavar*'s three-string array (3147 in^3) for **broadside** aspect, as a function of distance from the airguns, 21 July 2006, Chukchi Sea. Plotted as in Figure 4.6.

Comparison of Empirical and Modeled Radii for Airgun Sounds.—Table 4.4 summarizes the distances to a set of specified SELs and SPLs, as determined using the field measurements presented above for the one-string and three-string airgun arrays. These empirical distances are compared to distances predicted by sound propagation modeling (see Chapter 3). JASCO used their MONM acoustic model to generate SEL contours, from which SPLs were derived by Fourier synthesis analysis (see Chapter 3, Jensen et al. 2000). Because the contours produced by the MONM model are anisotropic (i.e., not distributed evenly in all directions), the predicted distances given in Table 4.4 are the radii encompassing 95% of the locations where the predicted SEL or SPL equals or exceeds the criterion value. For each array type, metric (SEL vs SPL), received level, and aspect (bow, stern, broadside) an "empirical : predicted" (E:P) ratio was calculated and is shown in Table 4.4.

Considering the SPL values (which are the ones used for mitigation purposes under current NMFS guidance), the empirical distances exceeded predicted distances in most (but not all) situations. For the *3-string array*, the E:P ratios for the 190-dB distance ranged from 1.5× to 2.0×, depending on aspect (Table 4.4A). The E:P ratios for the 180-dB distance around that array ranged from 1.2× to 1.7×. The ratios for the 160-dB distance ranged 1.5× to 1.8× (considering bow and stern aspect only). E:P ratios for the 120 dB

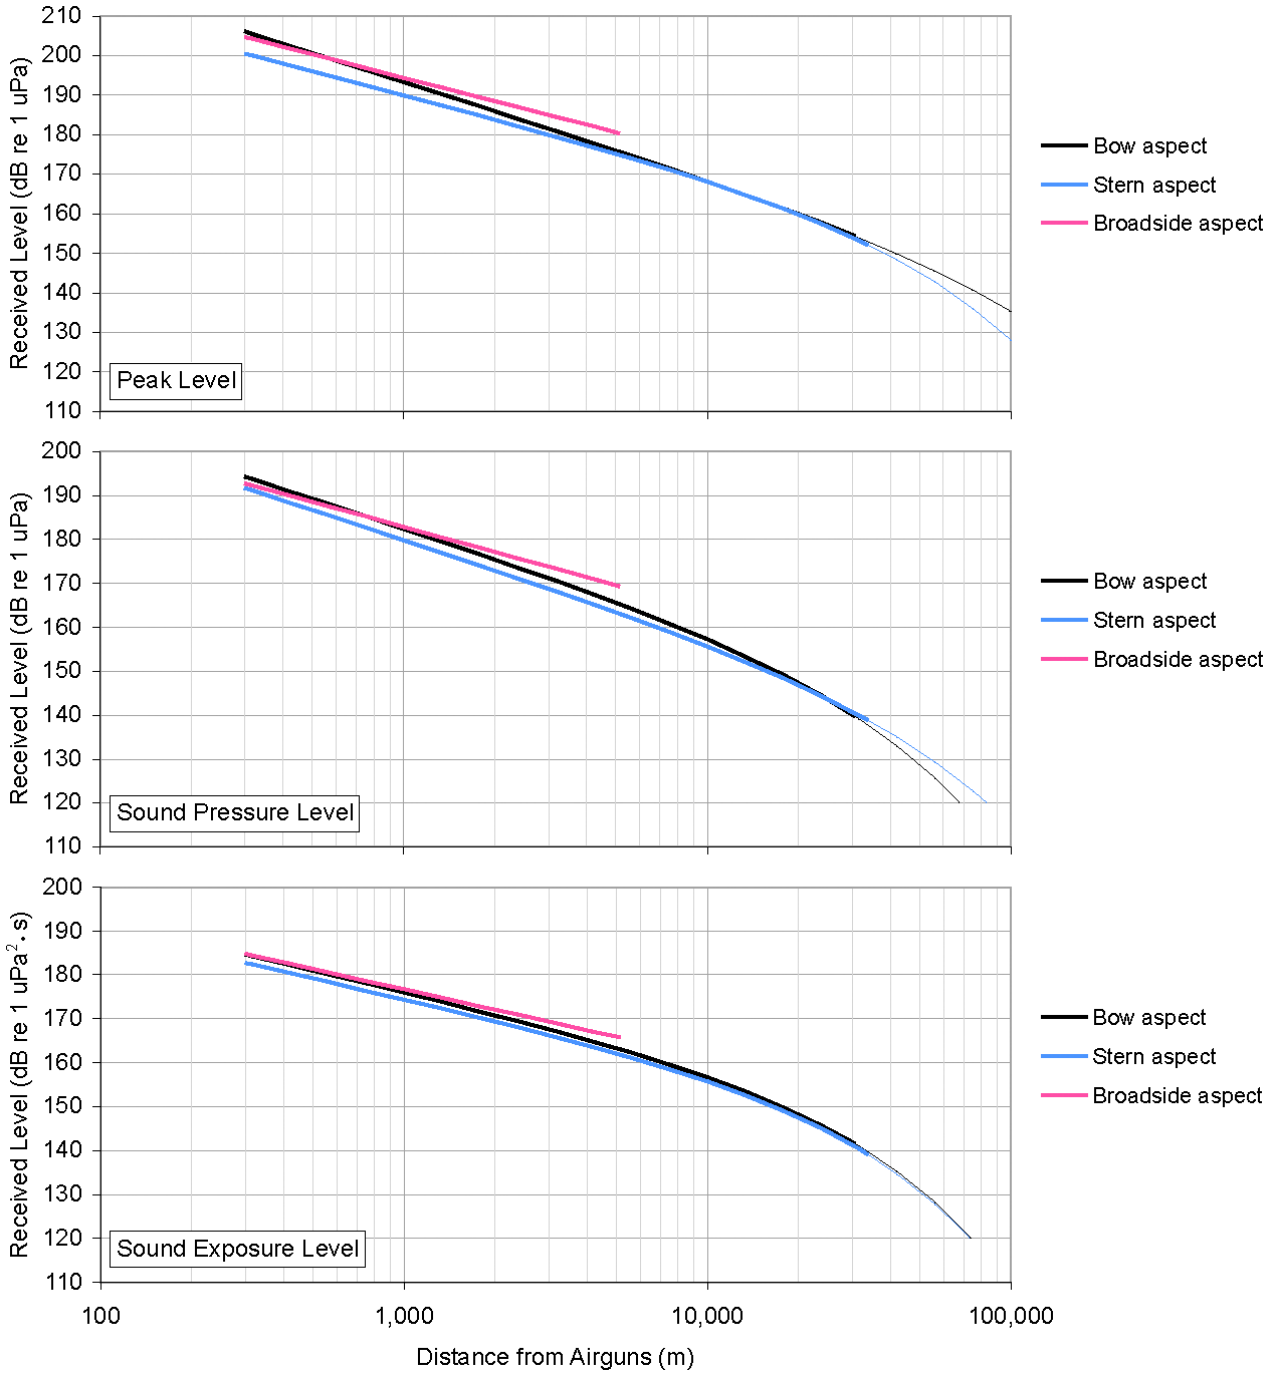

FIGURE 4.9. Summary of broadband levels for *Gilavar*'s three-string array configuration, 21 July 2006, Chukchi Sea. Data for all aspects are shown for peak (top plot), sound pressure (center plot), and sound exposure levels (bottom plot). Received levels which were obtained by extrapolating the regressions beyond the range of distances within which the measurements were made are indicated with a thinner line. Farthest measurement distances were 30.6 km, 33.9 km, and 5.2 km for bow, stern, and broadside data, respectively.

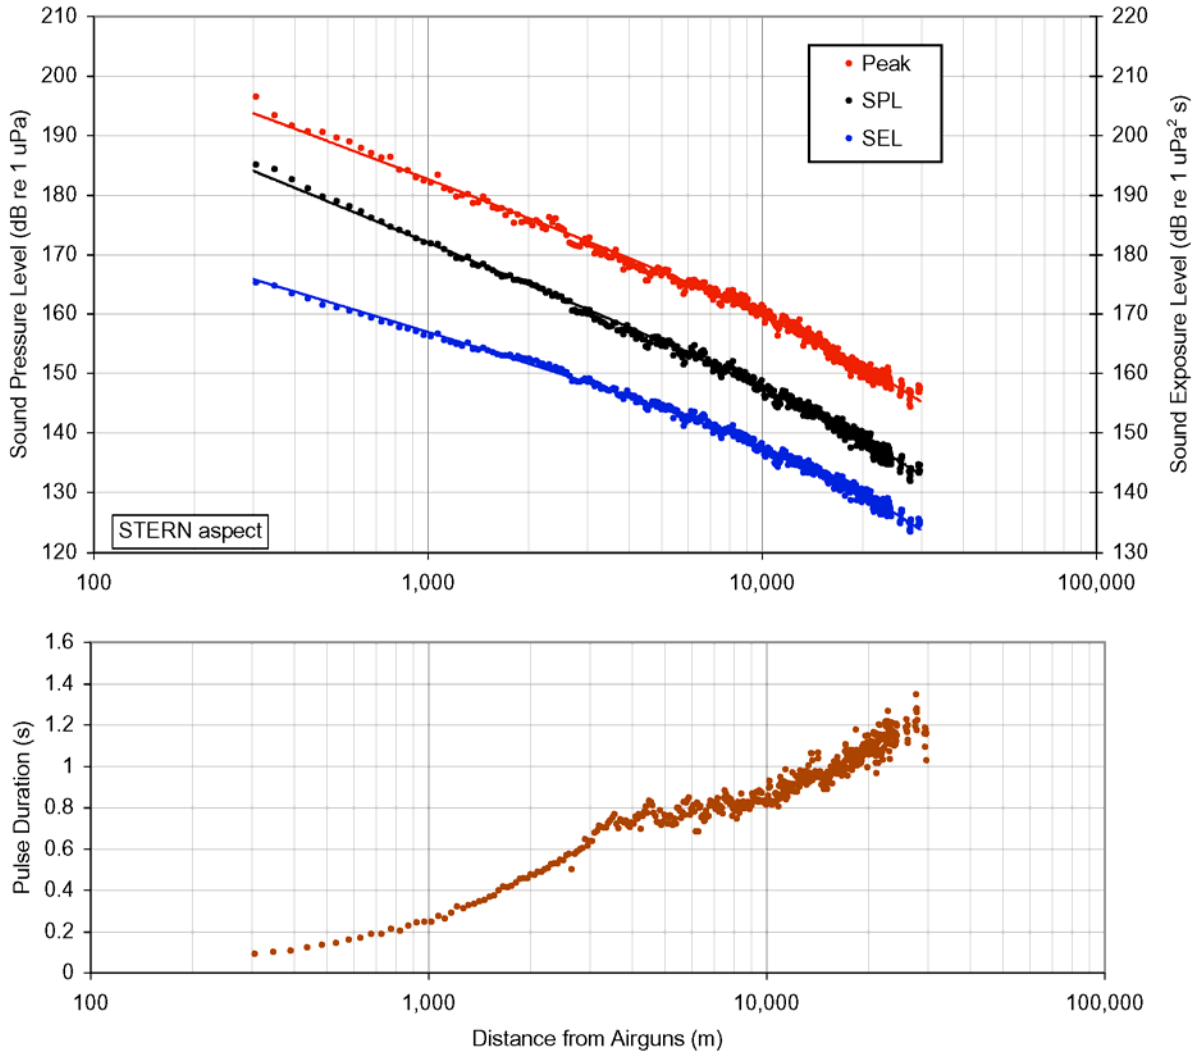

FIGURE 4.10. Received broadband levels of sound with *Gilavar*'s one-string array (1049 in^3) for **stern** aspect, as a function of distance from the airguns, 21 July 2006, Chukchi Sea. Equations for the regressions are given in Table 4.3. Otherwise plotted as in Figure 4.6.

distance were higher: 2.6× to 3.2× (again considering only bow and stern aspect). For the *single-string array*, the results also showed a tendency for higher E:P ratios when dealing with the 190 dB and 120 dB distances than when dealing with 160–180 dB distances. However, for the single-string array, the empirical distances were in fact less than the predicted distances (E:P < 1.0) in some cases (Table 4.4B). It should be noted that, because of ice conditions, the empirical measurements were taken at a location about 127 km from the C_1 site considered in JASCO's modeling. Differences in environmental conditions between those two sites probably accounted for some of the difference between empirical and predicted distances; the model would be expected to perform better if run for the actual site where the empirical measurements were acquired (D. Hannay, JASCO, pers. comm.).

Considering the SEL (energy) measure, the E:P ratios were higher than those for the SPL measure for almost all combinations of criterion level and aspect (Table 4.4). The underestimation of SEL levels by the model was particularly severe at the closer distances, i.e., those where the SEL value was 180–190

TABLE 4.3. Values for variables *A*, *B*, and *C* [Eq. (1) and (2)] in the regressions shown in Figures 4.10–4.12. Data were collected using the one-string airgun array in the Chukchi Sea. Values are shown for peak level, sound pressure level (SPL), and sound exposure level (SEL) for all three aspects (bow, stern, broadside). The multiple-*R* or *r*-value is also shown for each equation as well as the range of distances over which the measurements were made and the sample size (number of pulses analyzed).

	A	*B*	*C*	*R* (or *r*)	Range of distances (km)	Sample size
BOW					0.28–1.48	25
Peak	260.4	–24.94	N.A.	–0.992		
SPL	253.1	–25.99	N.A.	–0.992		
SEL	222.2	–17.87	N.A.	–0.991		
STERN					0.30–29.8	509
Peak	245.7	–20.94	$-2.25\ 10^{-4}$	–0.996		
SPL	240.6	–22.78	$-1.87\ 10^{-4}$	–0.997		
SEL	216.9	–16.54	$-3.06\ 10^{-4}$	–0.997		
BROADSIDE					0.17–1.16	7
Peak	247.2	–17.71	N.A.	(–0.998)		
SPL	242.2	–19.85	N.A.	(–0.999)		
SEL	210.7	–11.57	N.A.	(–0.997)		

dB re $(1\ \mu Pa)^2 \cdot s$. The SEL metric is not currently used for mitigation purposes, but would be used under the new procedures proposed by Southall et al. (submitted).

The fitted regressions resulting from Eq. (1) and (2) are based on a standard least-squares fit to the measured data, which means that about 50% of the empirical measurements fall above the line and 50% fall below (Fig. 4.6–4.8, 4.10, 4.11). Increasing the intercept value of each regression by 2 dB "elevates" each fitted curve by 2 dB, and nearly all the empirical measurements then are along or below the curves. Using these adjusted curves to determine mitigation radii results in protective radii that provide some margin for the inevitable variability in received levels. Table 4.5 is based on the same data as is Table 4.4, but the empirical distances are based on the curves with 2 dB added to all intercept values. The "E:P" ratios are larger in this case, as was to be expected when a protective factor was added to the empirical estimates but not to the model predictions.

Effect of M-weighting on Broadband SPLs and SELs.—Figure 4.14 illustrates the effects of *M*-weighting (as defined for mid-frequency cetaceans M_{mf}, pinnipeds in water M_{pw}, and low-frequency cetaceans M_{lf}) on SPLs (Fig. 4.14A) and SELs (Fig. 4.14B) for data collected in the Chukchi Sea. The amount (in dB) by which broadband (10–20,000 Hz) levels decreased as a result of being *M*-weighted is shown as a function of distance from the airguns. As expected given the varying low-frequency inflection points (f_{low}) for the three weighting functions, M_{lf} with $f_{low} = 7$ Hz had almost no effect on broadband SPLs or SELs, while M_{mf} with $f_{low} = 150$ Hz had the highest effect, and M_{pw} with $f_{low} = 75$ Hz had an intermediate effect. At close distances (400–650 m) pulse SPLs and SELs dropped by about 10 dB and 11 dB, respectively, for M_{mf}. At the same distance pulse SPLs and SELs dropped by about 5.5 dB and 6 dB,

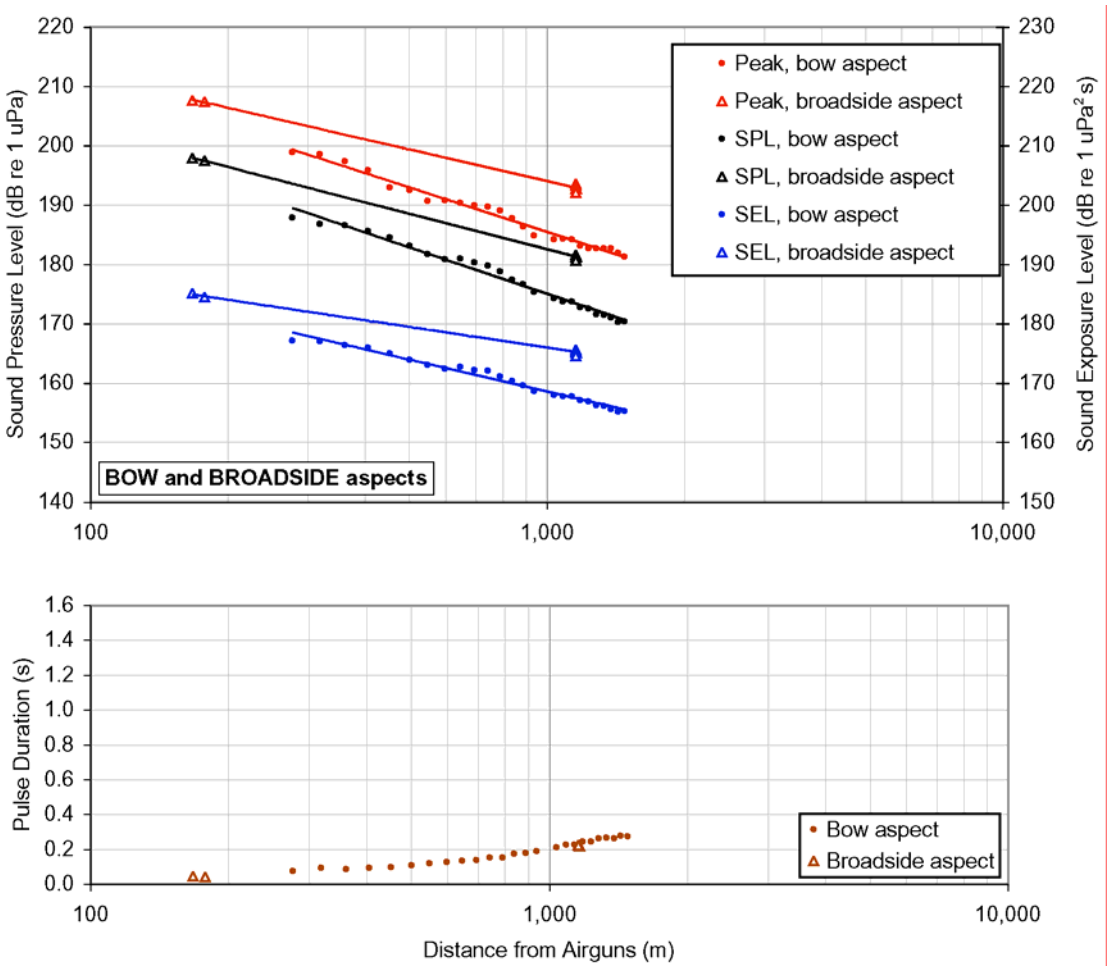

FIGURE 4.11. Received broadband levels of sound with *Gilavar*'s one-string array (1049 in^3) for **bow** (filled circles) and **broadside** (open triangles) aspects, as a function of distance from the airguns, 21 July 2006, Chukchi Sea. Plotted as in Figure 4.10.

respectively, for $M_{pw,}$. The effect of *M*-weighting decreased with distance from the sound source. At the farthest measurement distance, ~34 km, pulse SPLs and SELs dropped by less than 4 dB for M_{mf} and less than 2 dB for $M_{pw,}$. This was a result of the more rapid attenuation of the lower frequency components of the pulses with increasing distance.

To estimate how the 190 dB and 180 dB radii would change if *M*-weighted data were used instead of unweighted data, we fit two regressions to the points in Figure 4.14A, one for mid-frequency cetaceans and one for pinnipeds in water. The regressions were fitted to combined bow and stern aspect data. These represent the amounts (dB) by which SPLs drop as a result of M-weighting the data, as a function of distance from the airguns. For each distance (every m), we then subtracted the resulting decrease in SPL from the SPL regression shown in Figure 4.6 (bow aspect, three-string array) and reassessed the distances at which the 190 and 180 dB levels were reached. With unweighted data the 190 dB and 180 dB radii were 462 m and 1266 m, respectively (Table 4.4). For mid-frequency cetaceans (M_{mf}) these values decrease to 132 m and 455 m, respectively (28% and 36% of their former values, respectively). For pinnipeds in water (M_{pw}) these values decrease to 247 m and 776 m, respectively (53% and 61% of their former values, respectively).

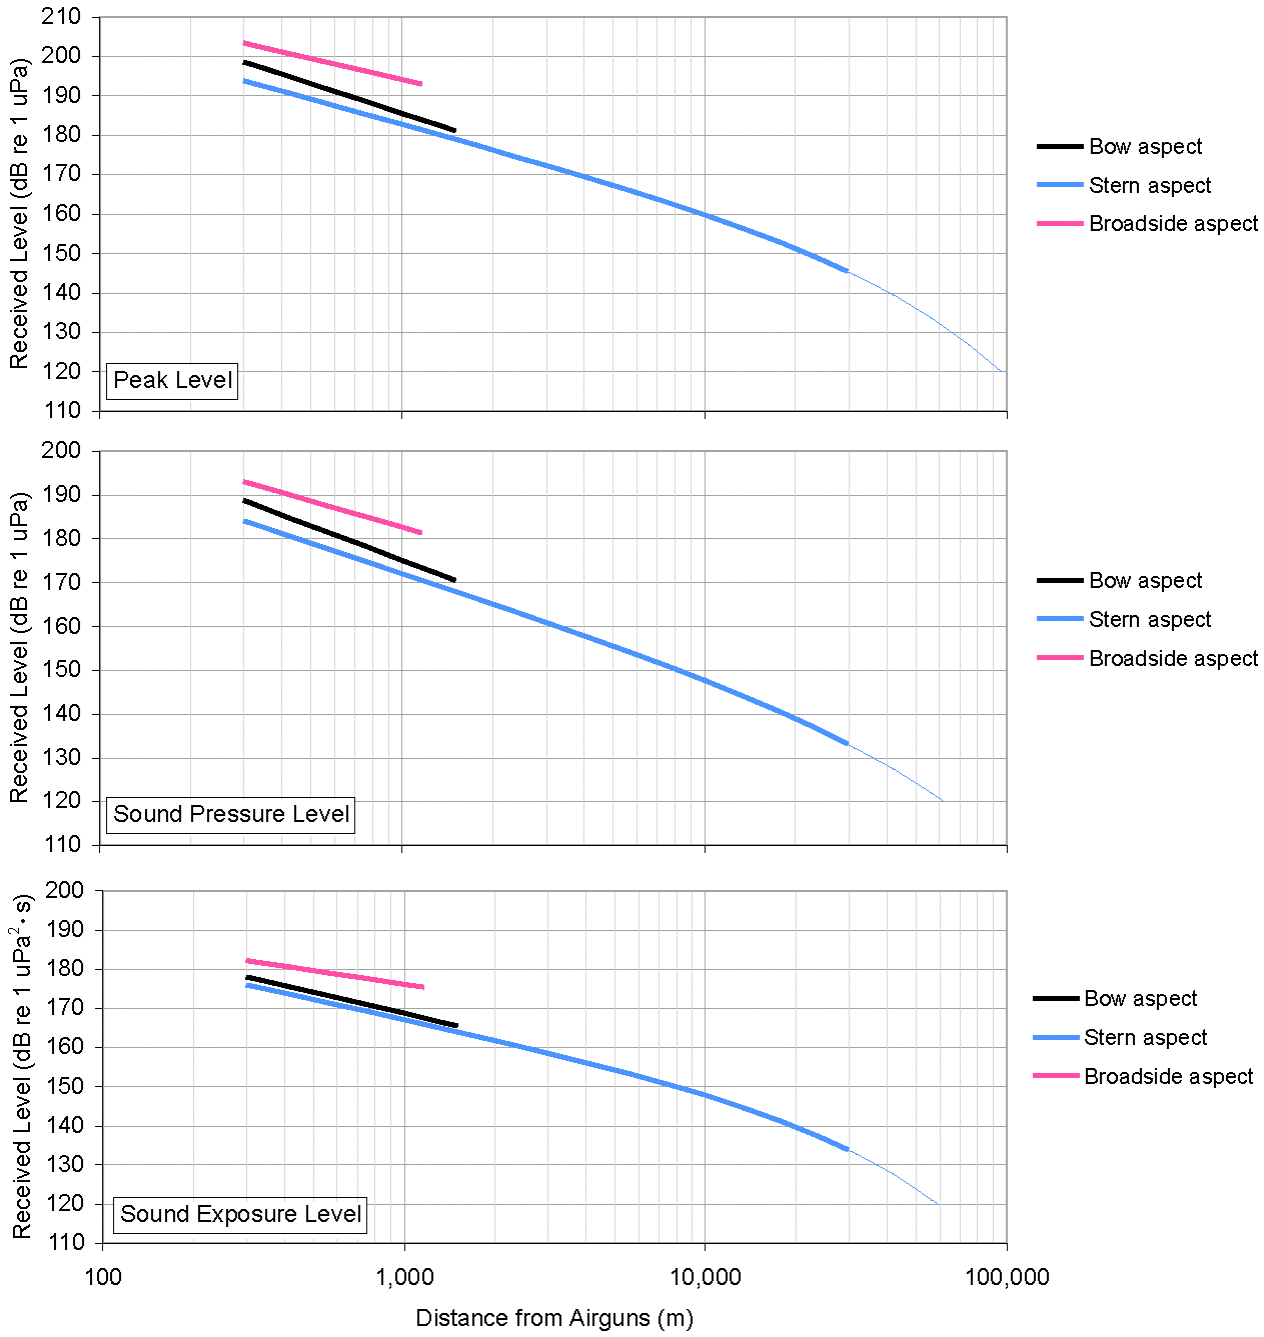

FIGURE 4.12. Summary of broadband levels for *Gilavar*'s one-string array configuration, 21 July 2006, Chukchi Sea. Data for all aspects are shown for peak (top plot), sound pressure (center plot), and sound exposure levels (bottom plot). Received levels which were obtained by extrapolating the regressions beyond the range of distances within which the measurements were made are indicated with a thinner line. Farthest measurement distances were 1.5 km, 29.8 km, and 1.2 km for bow, stern, and broadside data, respectively.

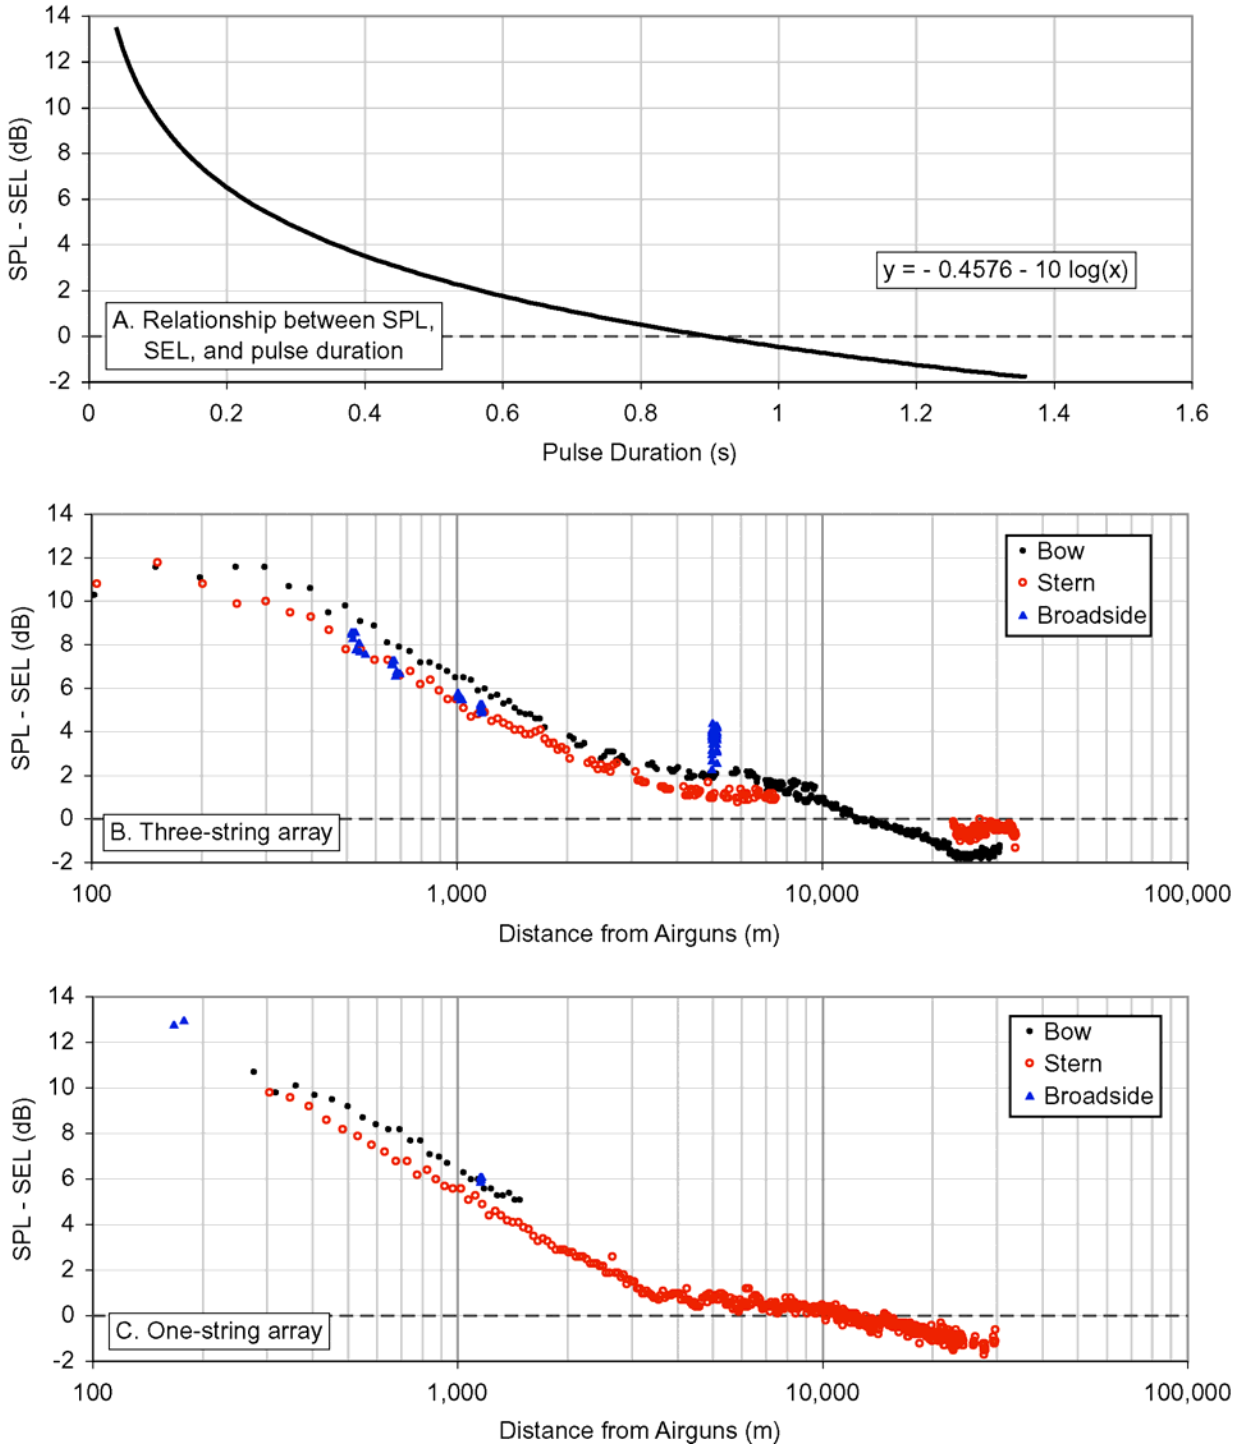

FIGURE 4.13. Relationship between SPL, SEL, pulse duration, and distance from *Gilavar*'s airguns for data collected in the Chukchi Sea. ***(A)*** SPL–SEL (i.e., the difference, for each analyzed pulse, in the received sound pressure level and sound exposure level) as a function of pulse duration. This relationship is defined mathematically as SPL–SEL = –0.4576–10 log(pulse duration). ***(B)*** SPL–SEL as a function of distance from the airguns for the three-string array data. ***(C)*** SPL–SEL as a function of distance from the airguns for the one-string array data.

TABLE 4.4. Distances to specified received sound exposure levels (SEL) and sound pressure levels (SPL) obtained with both array sizes used in the Chukchi Sea, and comparison with modeled values. All distances are in kilometers. C_1 is the site modeled by JASCO that most closely resembled the site where the empirical measurements were made. The "empirical : predicted" ratios were calculated with unrounded distances. For values shown in italics, the empirical distance was based on an extrapolation of the fitted curve beyond the range of the measured data.

	JASCO Predictions (km)	Empirical measurements (km)			"Empirical : Predicted" ratios

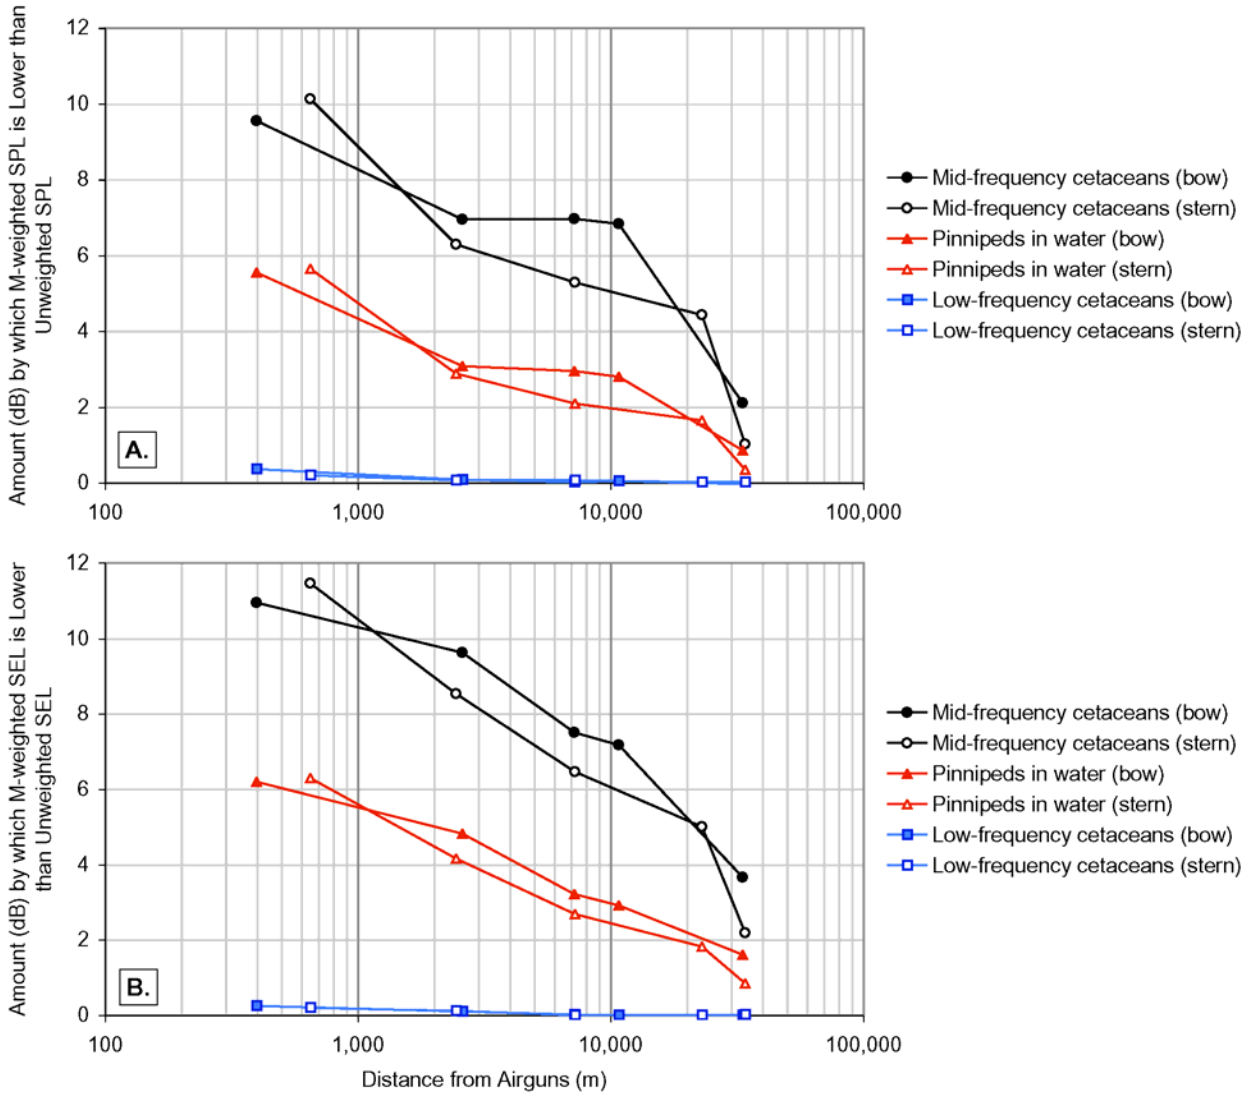

FIGURE 4.14. Effect of *M*-weighting on broadband levels, as a function of distance from the airguns (Chukchi Sea data). Both plots show the amount (dB) by which *M*-weighting decreases (A) pulse sound pressure levels (SPL) and (B) sound exposure levels (SEL). Three different types of *M*-weighting were used: for mid-frequency cetaceans (M_{mf}), pinnipeds in water (M_{pw}), and low-frequency cetaceans (M_{lf}). Each data point is the average of five consecutive pulses. Bow aspect data are distinguished from stern aspect data.

Broadband Levels for Shallow-Hazards Vessel Henry Christoffersen *(Beaufort Sea)*

On 8 August 2006, both ASARs were deployed in the locations given in Table 4.1, about 54 km east of Kaktovik off the north coast of Alaska. ASAR #1 was set to sample at 192 kHz (therefore filling its memory capacity in ~3 hours) and ASAR #2 at 44.1 kHz. Both ASARs started recording at 09:30 local time. The *Henry Christoffersen* followed a predetermined course over and away from the ASAR locations, providing endfire aspect data for various types of seismic sound sources. The *Henry C.*'s track is shown in Figure 4.15. The seismic and sonar sources were all operating simultaneously, but only on the outbound trip (away from the ASARs). While the sources were on, the *Henry C.* traveled at a speed of ~4 knots (7.4 km/h or 4.6 mph), using its two outer engines at reduced power (the two inner engines were turned off).

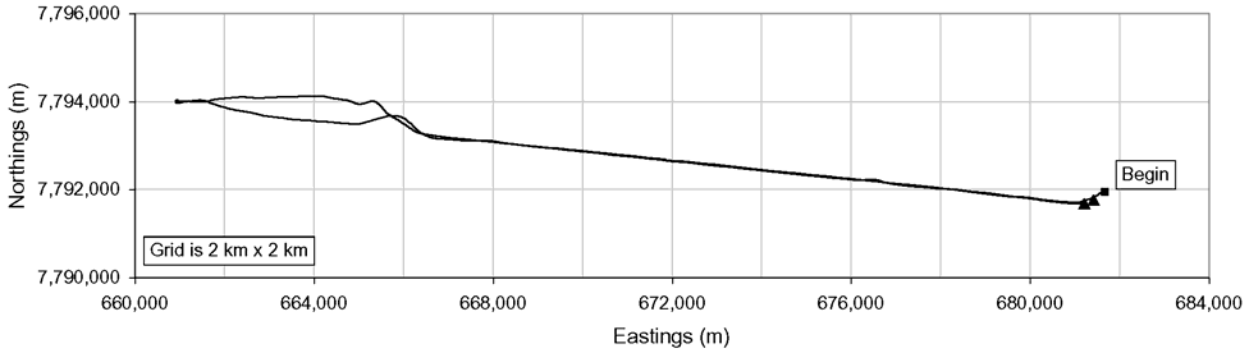

FIGURE 4.15. Track of the *Henry Christoffersen* during seismic, sonar, and vessel sound measurements. The grid squares are 2 km × 2 km. The *Henry C.* started its course at the filled square, steered over the two ASARs, then headed WNW at a speed of ~4 knots while seismic and sonar sound sources were turned on. On its return trip to the ASAR locations the *Henry C.* traveled at ~12 knots without any seismic or sonar sound sources turned on (see text for details). Filled triangles show the ASAR locations.

Airguns.—Figure 4.16 shows broadband levels for four pulse parameters as a function of distance from the Henry C.'s 4-airgun array: peak level, SPL, SEL and pulse duration. All aspects are combined, but the small, symmetric configuration of the four-gun array suggested there would be virtually no aspect dependence. For peak, SPL, and SEL values, Eq. (2) was fitted to the data. The resulting equations and multiple-*R* values are shown in Table 4.6. As expected, the received levels at a given distance were much lower for the small airgun array deployed from the *Henry C* than for the larger airgun arrays deployed from the Gilavar.

Comparison of Empirical and Modeled Radii for Airgun Sounds.—Table 4.7 summarizes the distances to a set of specified SELs and SPLs, as determined using the field measurements presented above for the *Henry Christoffersen*'s airgun array. These empirical distances are compared to distances predicted by sound propagation modeling (see Chapter 3). Note however that the empirical measurements were made with a 4-airgun 280 in^3 array whereas a 4-airgun 240 in^3 array was assumed in the modeling. JASCO used their MONM acoustic model to generate SEL contours, from which SPLs were derived by Fourier synthesis analysis (see Chapter 3, Jensen et al. 2000). Because the contours produced by the MONM model are anisotropic, the predicted distances given in Table 4.7 are the radii encompassing 95% of the locations where the predicted SEL or SPL equals or exceeds the criterion value. An "empirical : predicted" (E:P) ratio was calculated for each metric (SEL and SPL) and received level, as shown in Table 4.7. The E:P ratio was in general better (lower) for the Beaufort Sea measurements in Table 4.7 than the Chukchi Sea measurements in Table 4.4.

TABLE 4.6. Values for variables *A*, *B*, and *C* [Eq. (2)] in the regressions shown in Figure 4.16 for sounds from the airgun array towed by the *Henry Christoffersen*. Values are shown for peak level, sound pressure level (SPL), and sound exposure level (SEL) for all three aspects combined. The multiple-*R* value is shown for each equation as well as the range of distances over which the measurements were made and the sample size (number of pulses analyzed).

	A	*B*	*C*	Mult.-*R* value	Range of distances (km)	Sample size
					0.06–20.53	15
Peak	242.7	–21.70	$-6.31\ 10^{-4}$	–0.996		
SPL	233.4	–22.21	$-7.58\ 10^{-4}$	–0.993		
SEL	203.9	–15.72	$-7.47\ 10^{-4}$	–0.986		

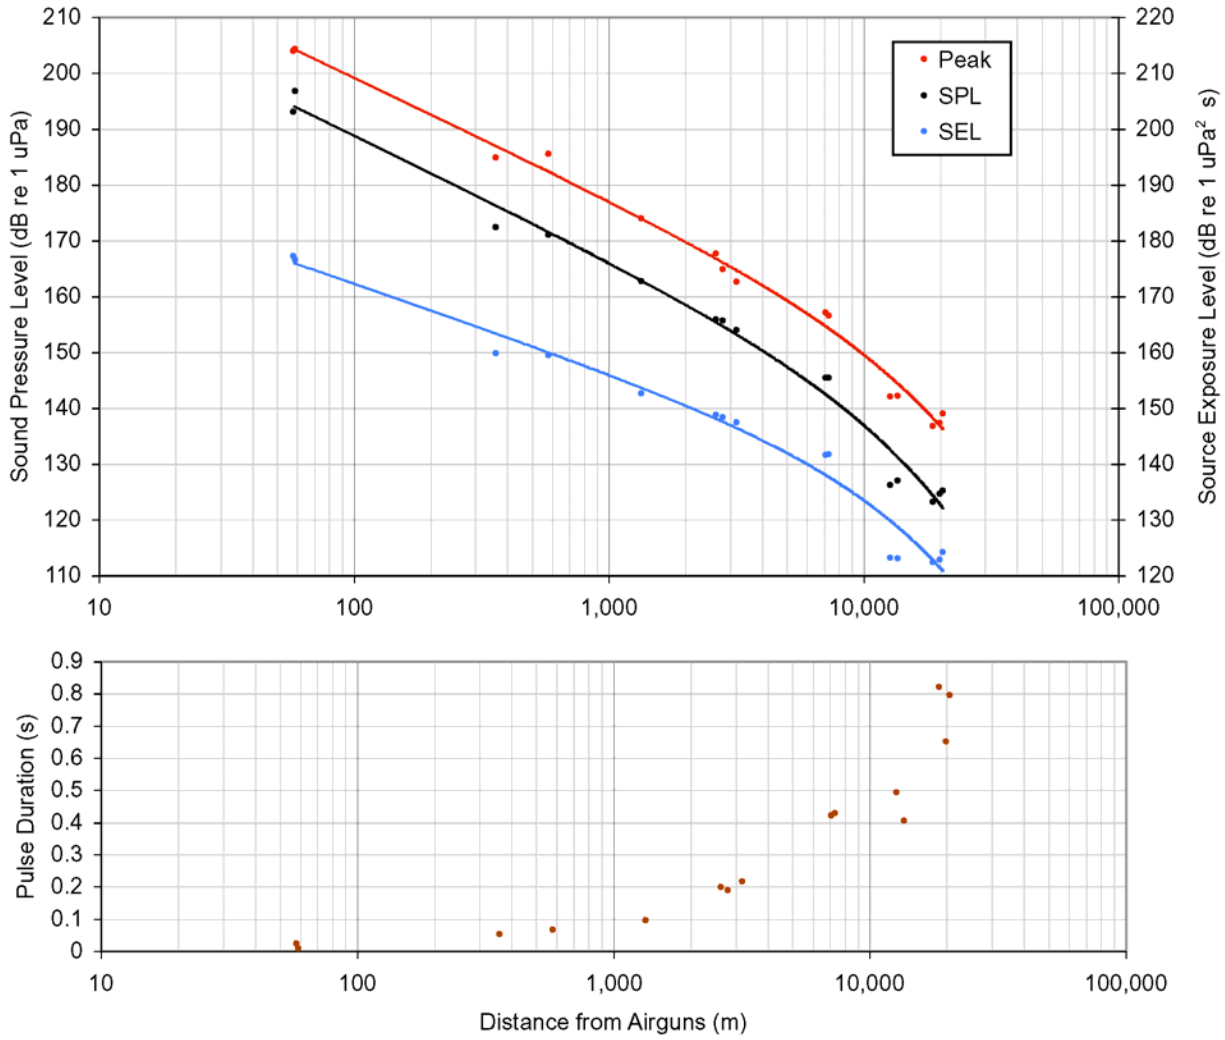

FIGURE 4.16. Received broadband levels of sound from airguns towed by the *Henry Christoffersen*, as a function of distance from the source (all aspects combined). The top plot shows peak levels and SPLs, with values to be read on the left y-axis (dB re 1 μPa), and SELs with values to be read on the right y-axis (dB re 1 $\mu Pa^2 \cdot s$). Note that to avoid overlap, values on the two y-axes are offset by 10 dB. Equations for the regressions are given in Table 4.5. The bottom plot shows pulse duration as a function of distance from the airguns.

The equations (Table 4.6) that resulted from fitting Eq. (2) to the empirical data were derived via a standard least-squares procedure, which means that about 50% of the empirical measurements fall above the line and 50% fall below. As for the Chukchi Sea, we calculated an alternate set of mitigation radii by increasing the intercept value of each regression in Table 4.6 so that almost all empirical data fall below the regression line. In the Chukchi data set, intercept values were increased by 2 dB. For the Beaufort measurements, we adjusted by 3 dB because of the somewhat greater variability in received levels at a given distance. These conservative radii and their comparison with the modeled ones are also shown in Table 4.7.

Chirp Sonar.—Received peak levels, SPLs, and SELs are shown in Figure 4.17 as a function of distance from the chirp sonar (sample size 73 pulses). Eq. (1) was fitted to the data for each parameter.

TABLE 4.7. Distances to specified received sound exposure levels (SEL) and sound pressure levels (SPL) obtained with 4-airgun array used in the Beaufort Sea, and comparison with modeled values. All distances are in kilometers. B_1 is the site modeled by JASCO that most closely resembled the site where the empirical measurements were made. However, modeling assumed a 240 in^3 array whereas the one used in the field was a 280 in^3 array. The "empirical : predicted" (E:P) ratios were calculated with unrounded distances. For values shown in italics, the empirical distance was based on an extrapolation of the fitted curve beyond the range of the measured data.

	JASCO Predictions (km)	Empirical Measure-ments (km)	E : P ratios
	B_1, 240 in^3		
SEL			
190 dB	0.005	*0.008*	*1.5*
180 dB	0.020	*0.033*	*1.6*
170 dB	0.055	0.14	2.6
160 dB	0.54	0.58	1.1
120 dB	23.42	*21.22*	*0.9*
SPL			
190 dB	0.02	0.089	4.5
180 dB	0.15	0.25	1.7
170 dB	0.30	0.68	2.3
160 dB	0.99	1.75	1.8
120 dB	35.98	*22.22*	*0.6*
SEL (with 3 dB added to intercept)			
190 dB	0.005	*0.012*	*2.4*
180 dB	0.020	*0.051*	*2.5*
170 dB	0.055	0.216	3.9
160 dB	0.54	0.87	1.6
120 dB	23.42	*24.08*	*1.0*
SPL (with 3 dB added to intercept)			
190 dB	0.02	0.12	6.1
180 dB	0.15	0.34	2.2
170 dB	0.30	0.91	3.0
160 dB	0.99	2.29	2.3
120 dB	35.98	*24.79*	*0.7*

Pulse durations are also shown as a function of distance from the sound source. Unlike seismic pulses (see Fig. 4.6–4.8, 4.10, 4.11 or 4.16), the durations of the "chirps" did not increase with distance, at least not over the small range of distances over which measurements were made (56–480 m).

Comparison of Empirical and Modeled Radii for Chirp Sonar.—The intercepts for both the SPL and SEL regressions (see Fig. 4.17) are below 190 dB so the data suggest that a 190 dB level was not reached at any distance from this source. However, there were no measurements at distances closer than

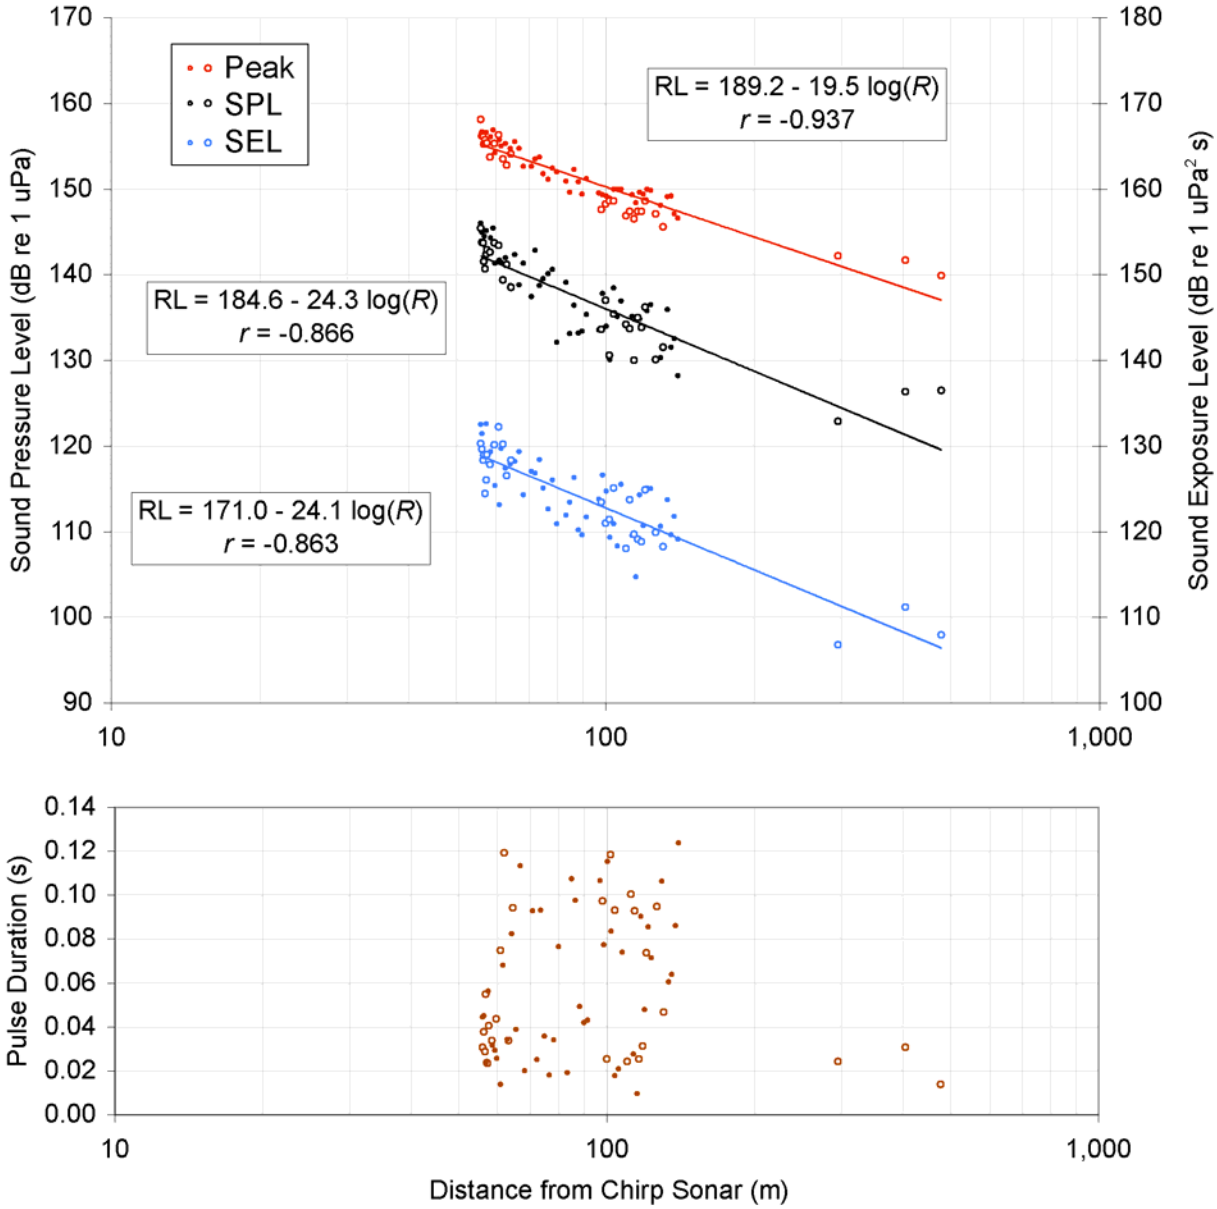

FIGURE 4.17. Received broadband levels of sound from chirp sonar towed by the *Henry Christoffersen*, as a function of distance from the source. The top plot shows peak levels and SPLs, with values to be read on the left y-axis (dB re 1 μPa), and SELs with values to be read on the right y-axis (dB re 1 $\mu Pa^2 \cdot s$). Filled circles are bow aspect data, open circles are stern aspect data. All data combined were used in the regressions. The bottom plot shows pulse durations as a function of distance from the chirp sonar.

~56 m, and no measurements were taken directly below the source. Using a ray tracing approach, JASCO estimated that 180 dB SPL would occur at a distance of 30 m for the B_1 location. This compares to an (extrapolated) estimate of ~1.6 m based on the empirical data shown in Figure 4.17.

Bubble-Pulser.—Received peak levels, SPLs, and SELs are shown in Figure 4.18 as a function of distance from the bubble pulser (sample size 48 pulses). Eq. (1) was fitted to the data for each parameter. Pulse durations are also shown as a function of distance from the sound source. As seen for the chirp sonar there was no change in pulse duration with distance. Bubble pulser sounds were of very short duration

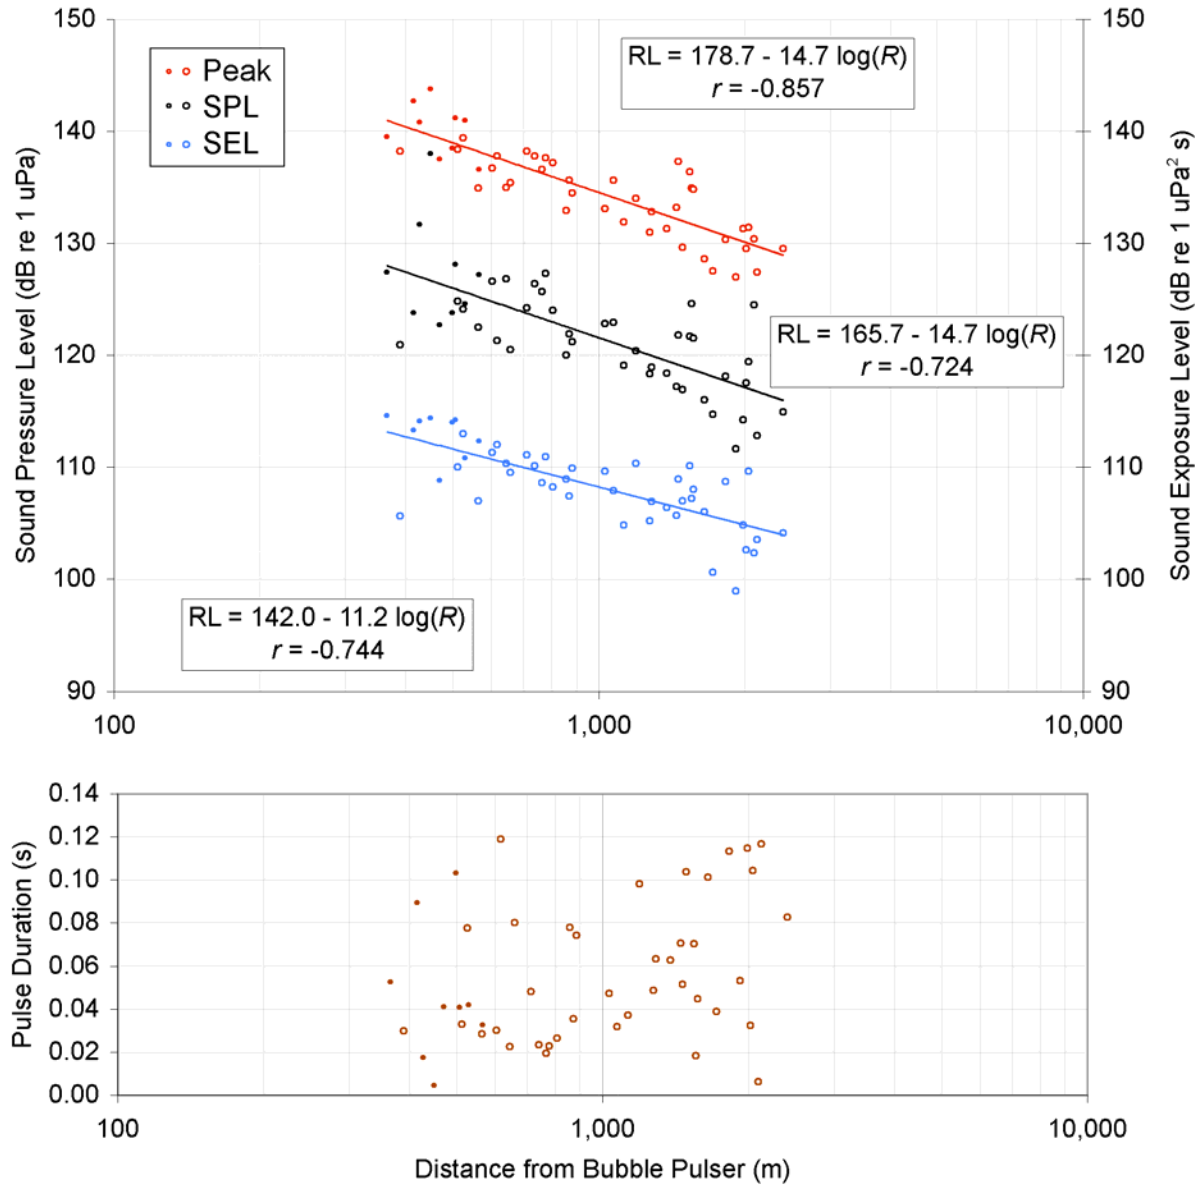

FIGURE 4.18. Received broadband levels of sound from bubble pulser towed by the *Henry Christoffersen*, as a function of distance from the source. The top plot shows peak levels and SPLs, with values to be read on the left y-axis (dB re 1 μPa), and SELs with values to be read on the right y-axis (dB re 1 $\mu Pa^2 \cdot s$). Filled circles are bow aspect data, open circles are stern aspect data. All data combined were used in the regressions. The bottom plot shows pulse durations as a function of distance from the bubble pulser.

(0.005 to 0.12 sec) and quite weak. Even for peak levels, the intercept of the regression (i.e., estimated nominal "source level" at 1 m) did not reach 180 dB re 1 μPa. However, there were no measurements at distances closer than ~56 m, and no measurements were taken directly below the source.

Spectral Analyses

Seismic Vessel Gilavar (Chukchi Sea).—Spectral density plots of seismic pulses at close and far ranges are presented in Figure 4.19. Each plot shows a broadside sample and an endfire sample taken at about the same distances. At close ranges (Fig. 4.19A) most of the pulse energy was below 300 Hz,

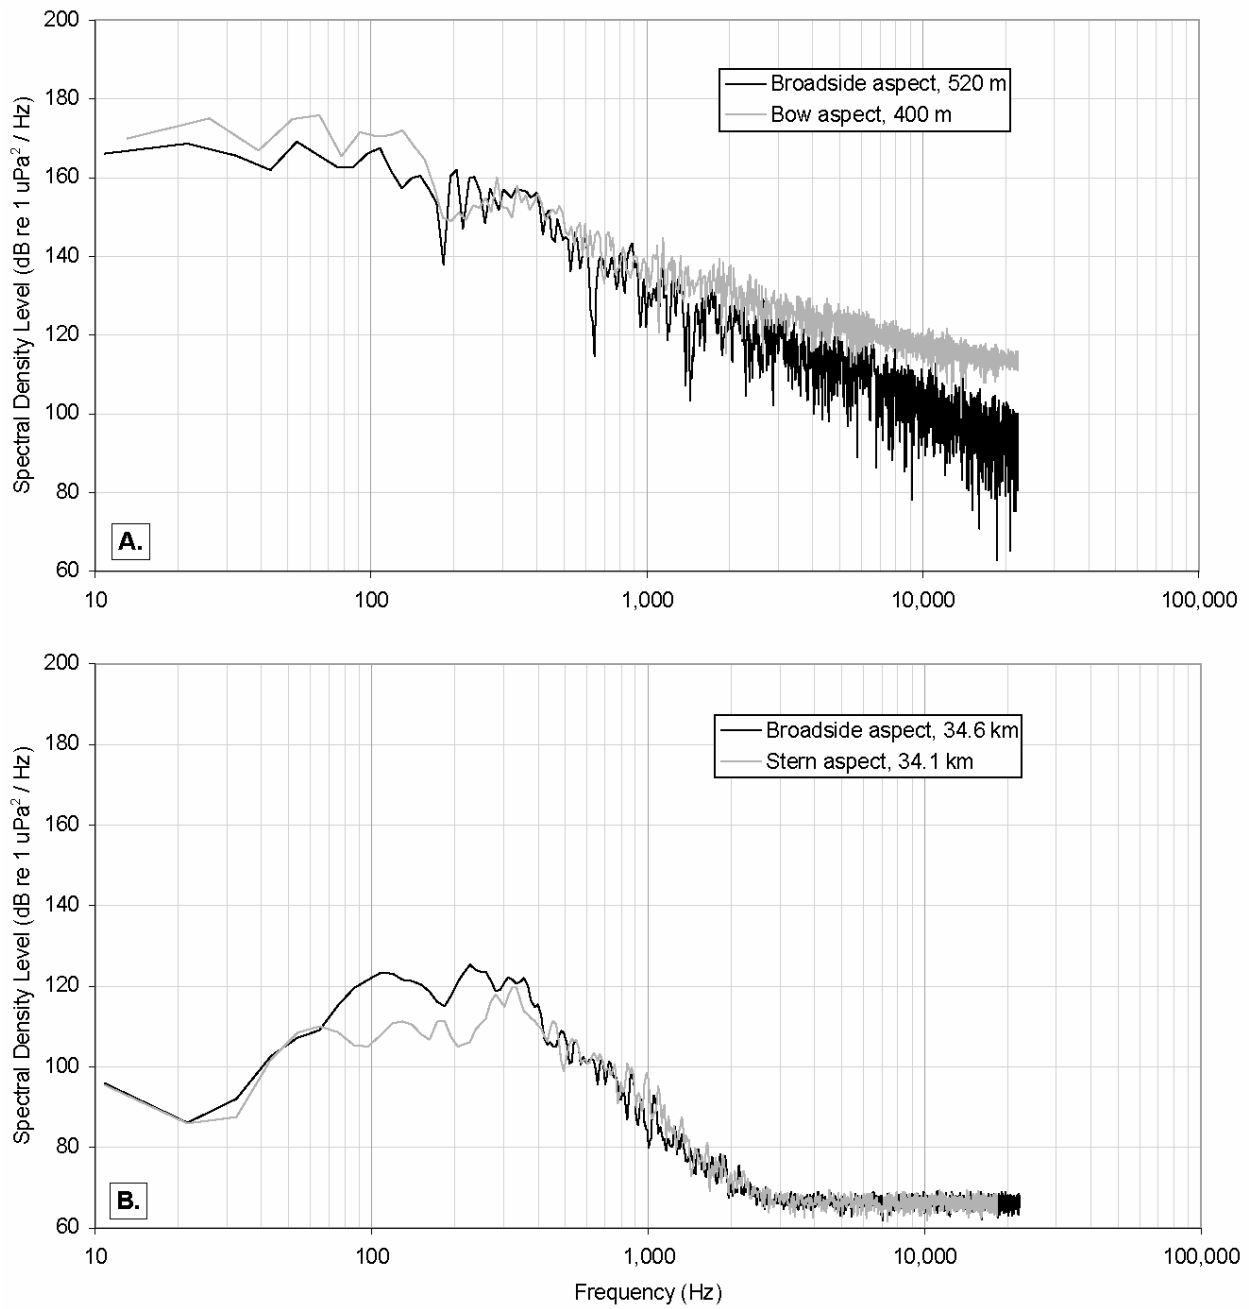

FIGURE 4.19. Spectral density levels for seismic pulses produced with the *Gilavar*'s three-string array, at ***(A)*** short ranges and ***(B)*** long ranges, 21 July 2006, Chukchi Sea. Two different aspects are shown in each plot. Each spectral density plot was produced by analyzing one typical pulse. FFT size was 4009 samples for all but the closest sample, for which it was 3392. This resulted in 11 and 13 Hz bin widths, respectively.

but there was still significant energy at higher frequencies. At the maximum measurement distance (~ 34 km), spectral density levels were lower at all frequencies, and most of the remaining pulse energy was between 70 and 400 Hz. Energy at higher and lower frequencies had attenuated (with distance) at a proportionally higher rate than occurred at 70–400 Hz.

Shallow-Hazards Vessel Henry Christoffersen (Beaufort Sea).—Spectral density plots of *airgun* pulses received at close and far ranges from the *Henry C.* are presented in Figure 4.20. The low-frequency components at close range could not be characterized because of the very short duration of the pulses received at that distance. In similar fashion to the seismic pulse measurements in the Chukchi Sea (Fig. 4.19), frequencies below ~70 Hz and above ~700 Hz have been attenuated in the distant sample (20.5 km).

The *chirp sonar* produced a 50 ms linear sweep of two sinusoids at frequencies of 2–7 and 8–23 kHz. This can be seen in Figure 4.21, showing a 0.13 s spectrogram of the chirp sonar sound source.

A spectral density plot of a pulse from the *bubble pulser* is shown in Figure 4.22. The bubble pulser was described as having most of its energy close to 400 Hz. The short duration of the pulse shown (0.04 s) resulted in low resolution (47 Hz) at the frequencies of interest. The spectral density plot shows a dip at 400 Hz, surrounded by two peaks, one at ~280 Hz and the other at ~610 Hz.

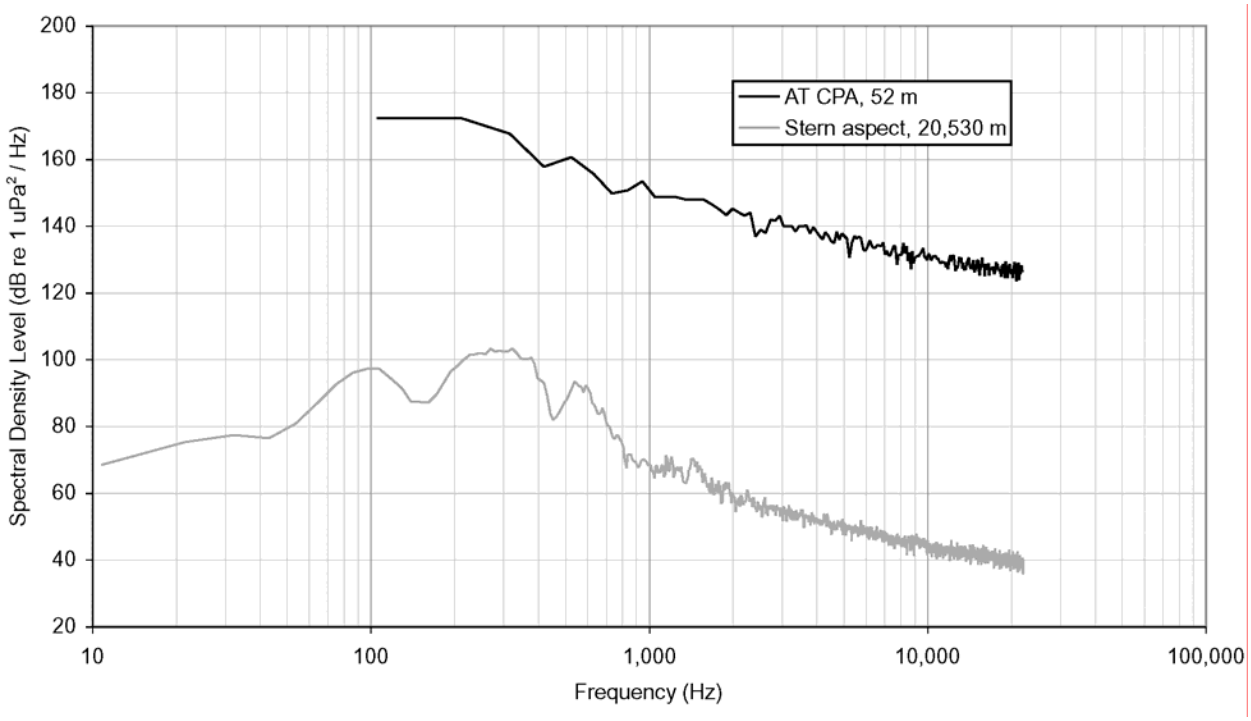

FIGURE 4.20. Spectral density levels for seismic pulses produced by the airgun array towed by the *Henry Christoffersen* at short and long range, 8 August 2006, Beaufort Sea. Each spectral density plot was produced by analyzing one typical pulse. FFT size was 420 and 4096 samples for the close and far pulse, respectively (the small FFT size was necessary for the CPA pulse, which was of extremely short duration). This resulted in 105 and 11 Hz bin widths, respectively.

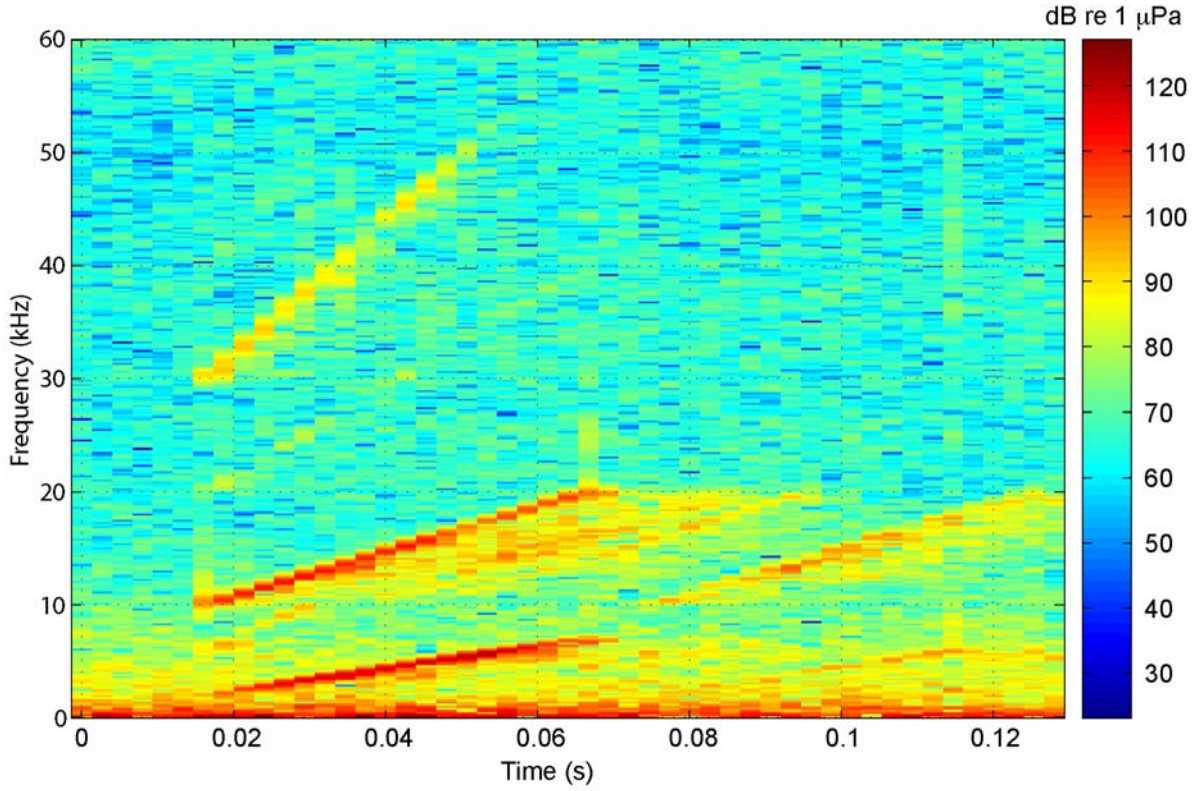

FIGURE 4.21. Spectrogram of the chirp sonar towed behind the *Henry Christoffersen*. This 0.13 sec sample was taken at the closest point of approach (56 m). The scale is in dB re 1 μPa.

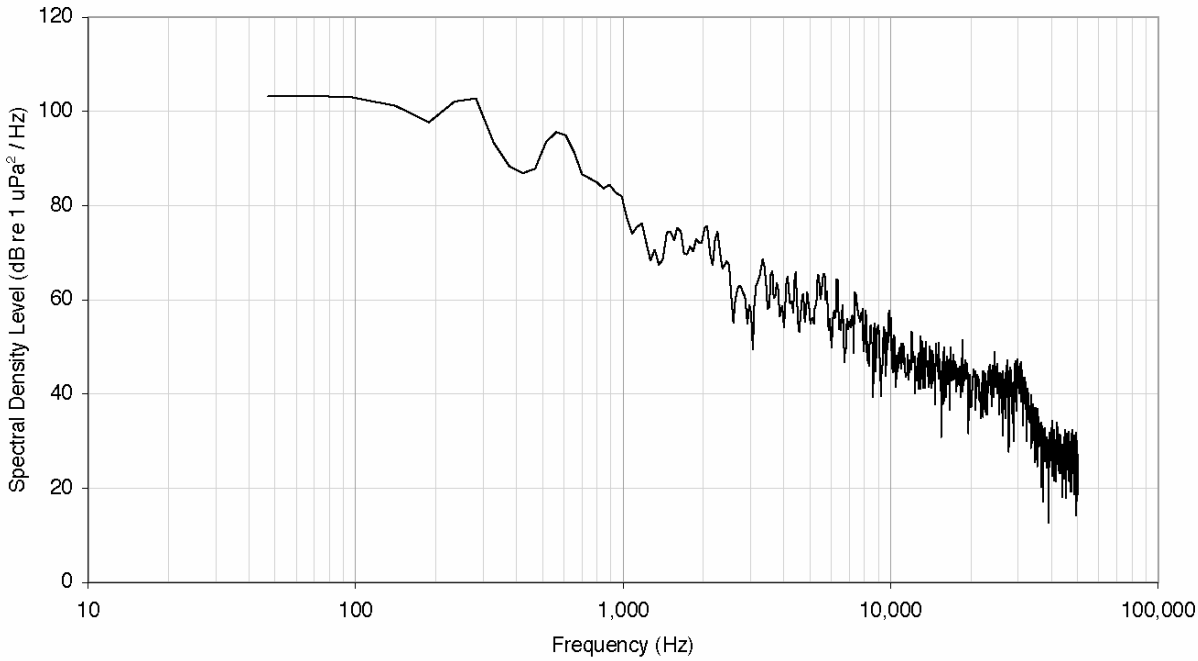

FIGURE 4.22. Spectral density levels for bubble pulser towed by the *Henry Christoffersen* at short range, 8 August 2006, Beaufort Sea. The spectral density plot was produced by analyzing one typical pulse 140 m from ASAR #1. FFT size was 4096 samples, resulting in a 47 Hz bin width. The short duration of the pulse limited the size of the FFT that could be used, and therefore low resolution at the frequencies of interest.

Vessel Sound Measurements

Measurement Circumstances

Gilavar and Kilabuk.—On 12 July 2006 both ASARs were deployed in the Chukchi Sea in the locations shown in Table 4.1. After deployment the *Kilabuk* and then the *Gilavar* followed a predetermined route over and away from the ASAR locations, to provide recordings of the vessel sounds from different distances and different aspects (bow, stern, broadside). As an example, the route taken by the *Gilavar* is shown in Figure 4.23. It is similar to the course followed during airgun sound measurements, but on a smaller scale (maximum distance from the ASARs was ~10 km, as opposed to ~30 km during the airgun sound measurements). The *Kilabuk* and *Gilavar* were traveling at speeds of ~10 and 12 knots (18.5 and 2.2 km/h, or 11.5 and 13.8 mph), respectively. The vessels passed over ASAR #2 in both directions[8] (eastward and westward) to provide bow and stern aspect data. They then zigzagged back and forth at several distances from the recorders to provide broadside data (see Fig. 4.23). While the *Kilabuk* followed its course the *Gilavar* idled 5.6 km southeast of the ASAR location. While the *Gilavar* followed its course the *Kilabuk* idled 9.3 km northwest of the ASAR location.

Henry Christoffersen.—On 8 August 2006 both ASARs were deployed in the Beaufort Sea in the locations shown in Table 4.1. The *Henry C.*'s course is shown in Figure 4.15. The vessel passed close to the ASARs[4] before heading WNW. On the outward (westerly) leg seismic and sonar sources were operating, and the ship was cruising at a speed of ~4 knots. On the return (easterly) leg the seismic sources were turned off and the ship was traveling at a speed of ~12 knots (22.2 km/h or 13.8 mph) with all four engines running. The vessel sound measurements presented in this report were taken from the return leg.

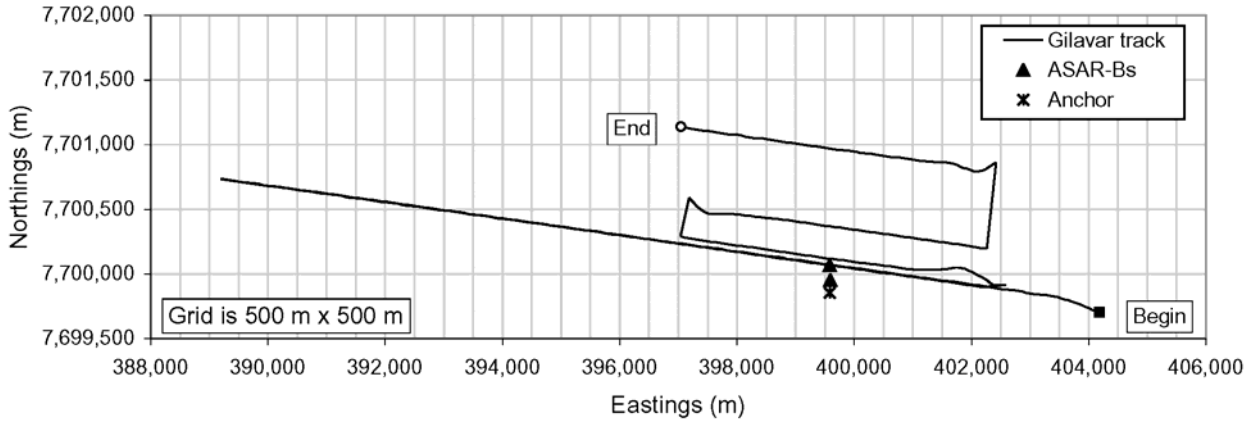

FIGURE 4.23. Track of the M/V *Gilavar* during vessel sound measurements. The grid squares are 500 m × 500 m; the map has been extended in the N-S direction to better show the ship track. The track starts at the filled square and ends at the open circle. Filled triangles show the ASAR locations. The first two runs (west and then east) were on top of each other and over ASAR #2 and provided bow and stern aspect data. The remaining runs provided broadside aspect data.

[8] Both the *Kilabuk* and the *Henry Christoffersen* missed passing directly over one or both ASAR-Bs.

Broadband Levels

Kilabuk and Gilavar.—Broadband (10–20,000 Hz) levels, as calculated for each non-overlapping 1-s segment throughout the entire vessel sound measurement session, are shown in Figure 4.24 as recorded by the ITC 1032 hydrophone on ASAR #2. The large spikes in received levels correspond to each vessel's closest points of approach during consecutive passes by the ASARs (see Fig. 4.23). Heightened levels indicated by diamonds correspond to the *Gilavar* turning around. Note that minimum ("background") levels during the *Gilavar's* run were lower than during the *Kilabuk's* run.

Broadband (10–20,000 Hz) levels are shown as a function of distance from the source in Figure 4.25 for the *Kilabuk* and in Figure 4.26 for the *Gilavar*. Data from both hydrophone types are mixed in these plots, with data from the ITC 1032 and ITC 8212 hydrophones used at received levels above and below ~125 dB re 1 μPa, respectively. These data are presented as a function of aspect: bow, stern, or broadside. Eq. (1) was fitted to each data set and the resulting equations are shown in each plot. When computing these regressions, data at increasing distances from the sound source were included until the broadband levels reached a minimum and remained constant. For example, broadband levels for the *Kilabuk* (Fig. 4.25) apparently reached background levels 2–3 km from the recorders. For both vessels, bow-aspect data in the near-field (less than 300 m) were also erratic and were excluded when fitting the curves.

Henry Christoffersen.— Broadband (10–20,000 Hz) levels are shown as a function of distance from the *Henry C.* in Figure 4.27. These are bow aspect data (ASAR #2, ITC 8212 hydrophone) obtained during the *Henry C.*'s eastward return trip to the ASAR locations (see Fig. 4.15), while seismic and sonar sources were turned off and the ship was traveling at 10–12 knots. Eq. (1) was fitted to the data acquired from distances up to 10 km, beyond which broadband levels remained constant and had presumably reached background values. The discontinuity in received levels at 9–10 km coincides with a sudden shift in water depth from ~45 to ~41 m.

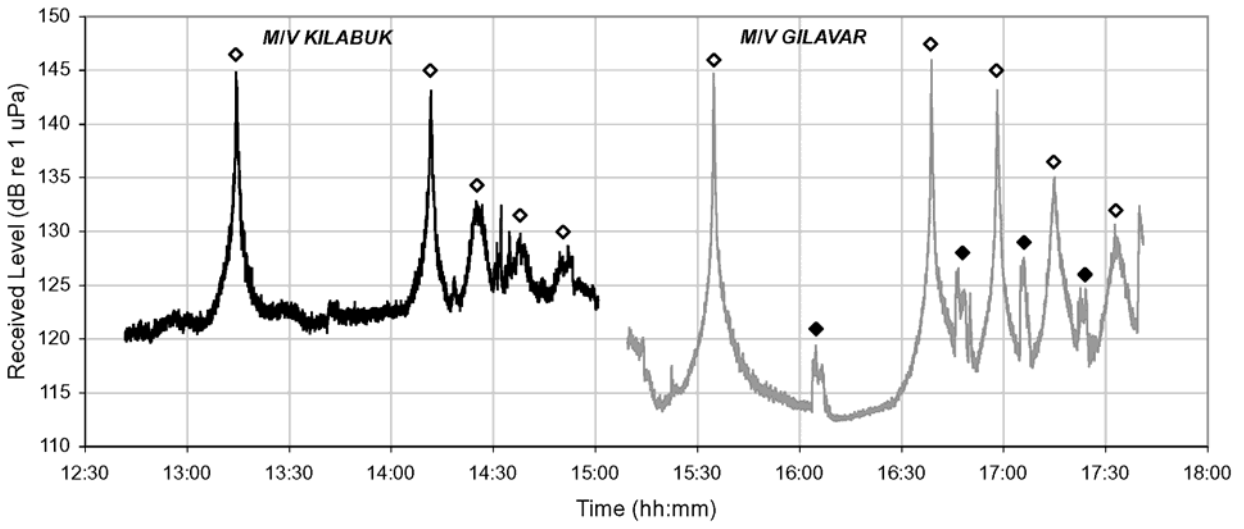

FIGURE 4.24. Broadband levels (one value for each 1-s interval) of vessel sounds as recorded by the ITC 1032 hydrophone (less sensitive) on ASAR #2, Chukchi Sea, 12 July 2006. The *Kilabuk* followed its track between 12:45 and 15:00 while the *Gilavar* stood by. Between 15:15 and 17:45 the *Gilavar* followed its track (see Fig. 4.20) while the *Kilabuk* stood by. Open diamonds indicate times when the vessels were at their closest points of approach to the ASARs on each pass. Closed diamonds indicate times when the *Gilavar* was turning around.

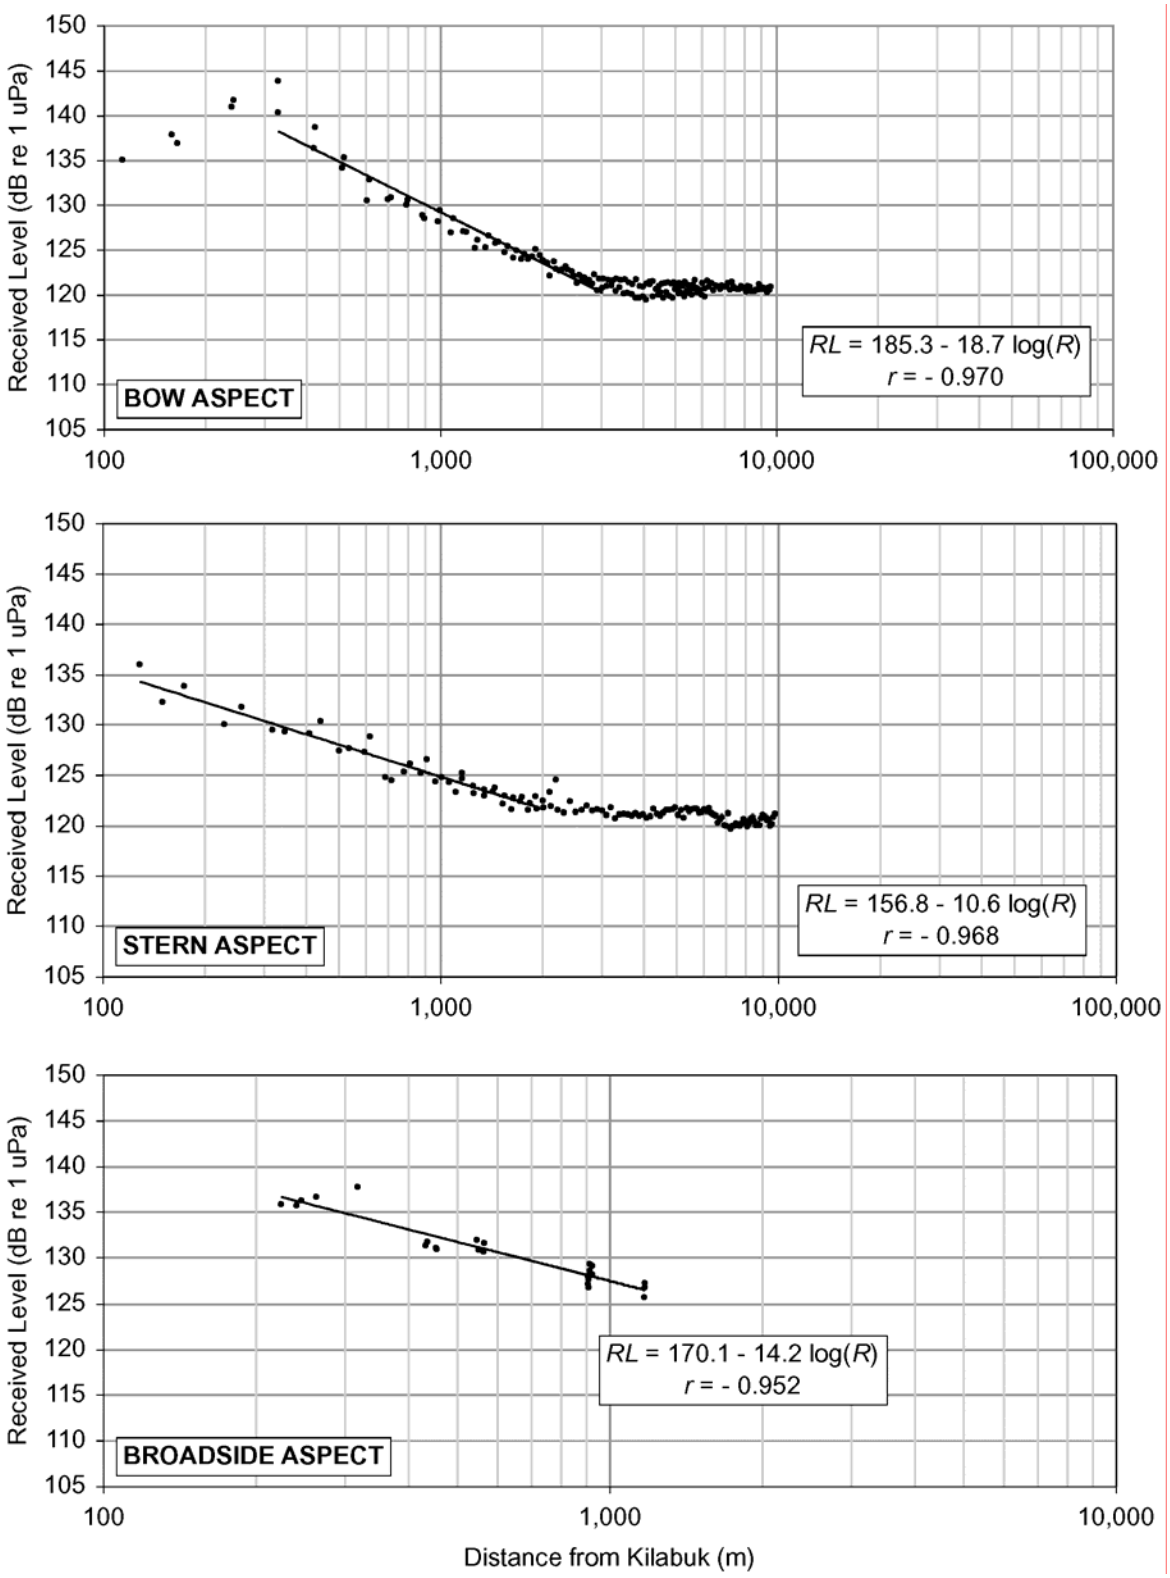

FIGURE 4.25. Broadband levels (10–20,000 Hz) of vessel sounds as a function of distance from the *Kilabuk*, for bow aspect (top), stern aspect (center), and broadside aspect (bottom). The regressions shown were calculated using data over the following ranges: ~300–3000 m for bow aspect, 100–2000 m for stern aspect, all data for broadside aspect (see text).

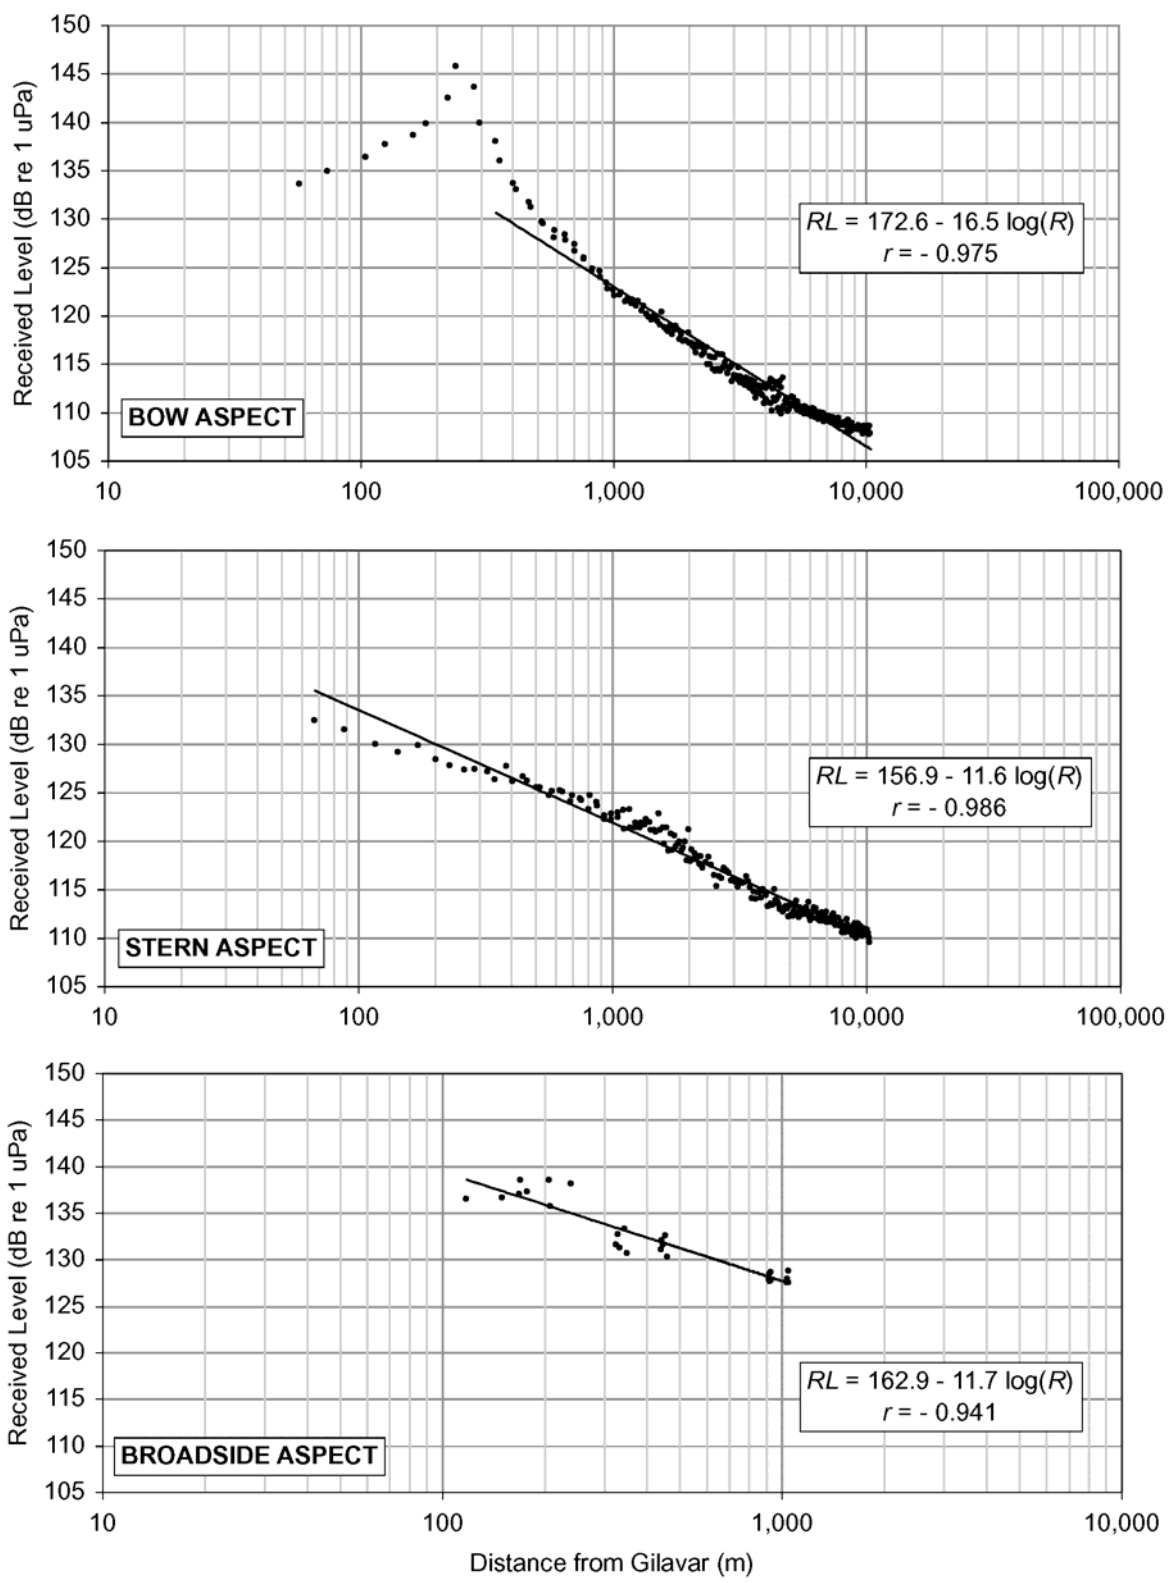

FIGURE 4.26. Broadband levels (10–20,000 Hz) of vessel sounds as a function of distance from the *Gilavar*, for bow aspect (top), stern aspect (center), and broadside aspect (bottom). The regressions shown were calculated using data over the following ranges: ~300–10,000 m for bow aspect, all data for stern and broadside aspects (see text).

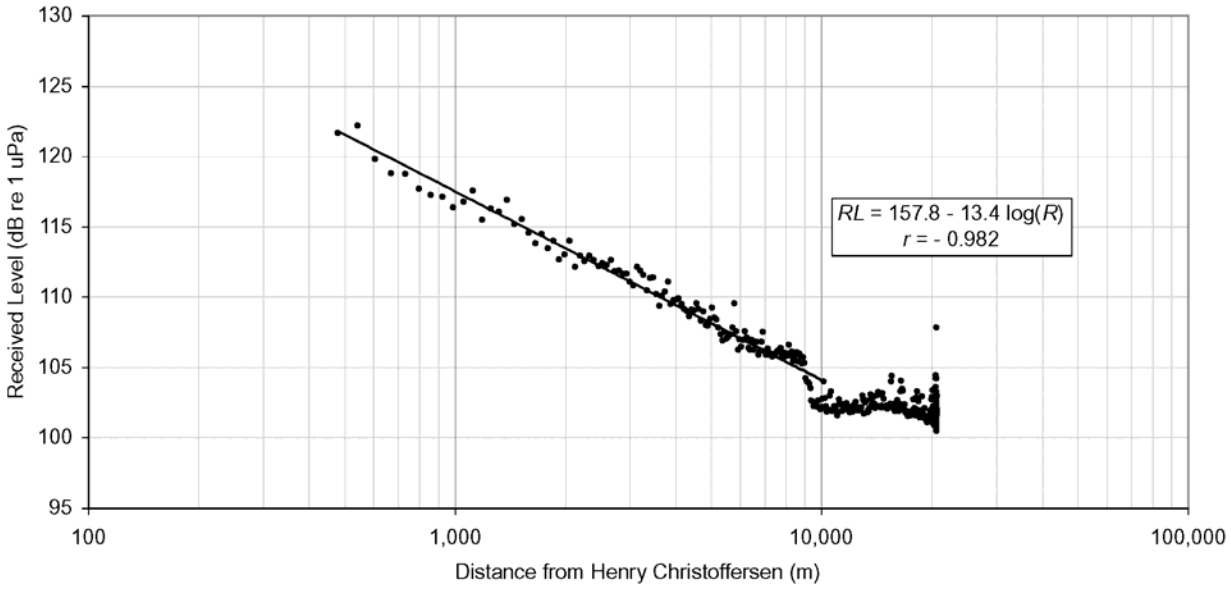

FIGURE 4.27. Broadband levels (10–20,000 Hz) of vessel sounds as a function of distance from the *Henry Christoffersen*.

Spectral Analyses

Kilabuk and Gilavar.—To describe the "sound signature" of each vessel, spectral analyses were performed on 10 s samples from recordings obtained when the vessels were close to the ASARs (i.e., with a high signal to background noise ratio). The results from these analyses are shown in Figures 4.28 and 4.29, showing one-third octave band levels and sound spectral density levels (respectively) for both ships. The *Gilavar* produced two large peaks at 15 and 31 Hz, and then several peaks at higher frequencies (359, 622, 1129, and 1246 Hz). The *Kilabuk* produced a series of peaks at low frequencies (32, 42, 45, 53, 67, 90, and 100 Hz).

Henry Christoffersen.—Spectral density levels for a 10 s sample while the *Henry C.* was about 310 m from the ASAR are shown in Figure 4.30. Again there are large peaks at low frequencies, 16–17 Hz, 47 Hz, and 93–94 Hz.

Sound Speed Profiles

Figure 4.31 shows sound speed profiles for the three sampling areas presented in this report: the locations of the recorders for the seismic measurements in the Chukchi Sea, the vessel sound measurements in the Chukchi Sea, and the seismic and vessel sound measurements in the Beaufort Sea. These profiles are relevant in assessing propagation of sound in each sampling area, and may be important in any future modeling or interpretation of the results presented above.

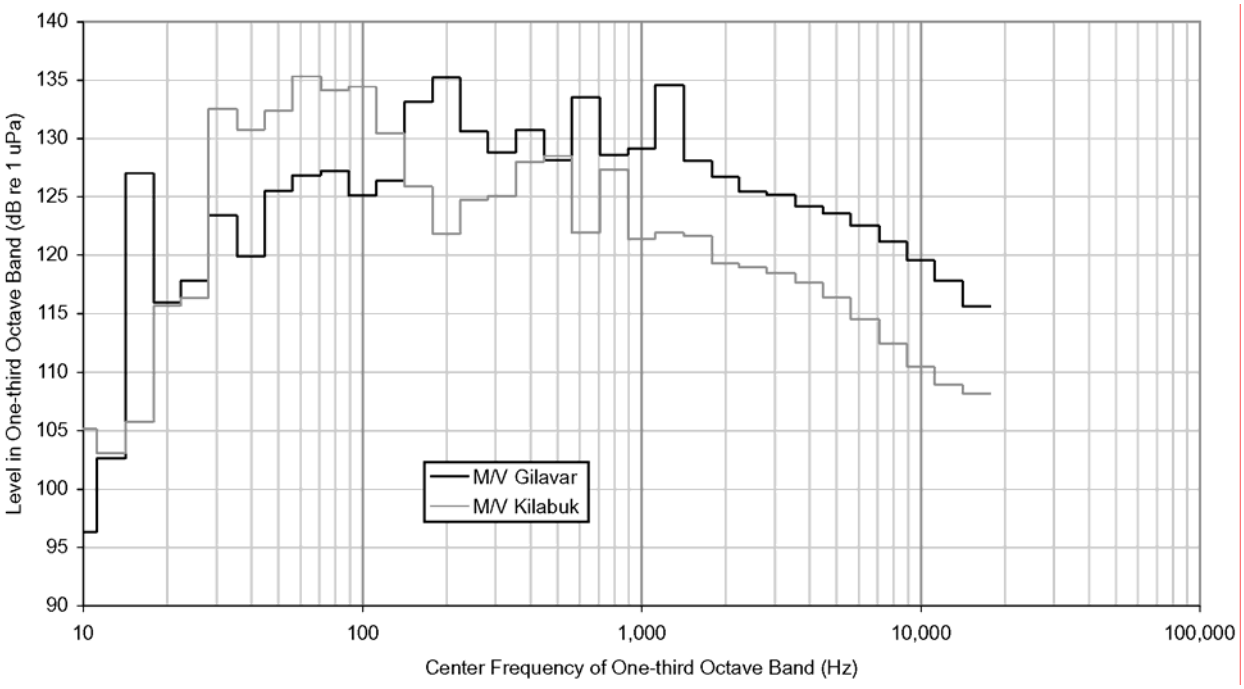

FIGURE 4.28. One-third octave band levels of vessel sounds for the *Gilavar* (black line) and *Kilabuk* (gray line). For each vessel, a 10 s sample was analyzed, taken at each vessel's closest point of approach to ASAR #2.

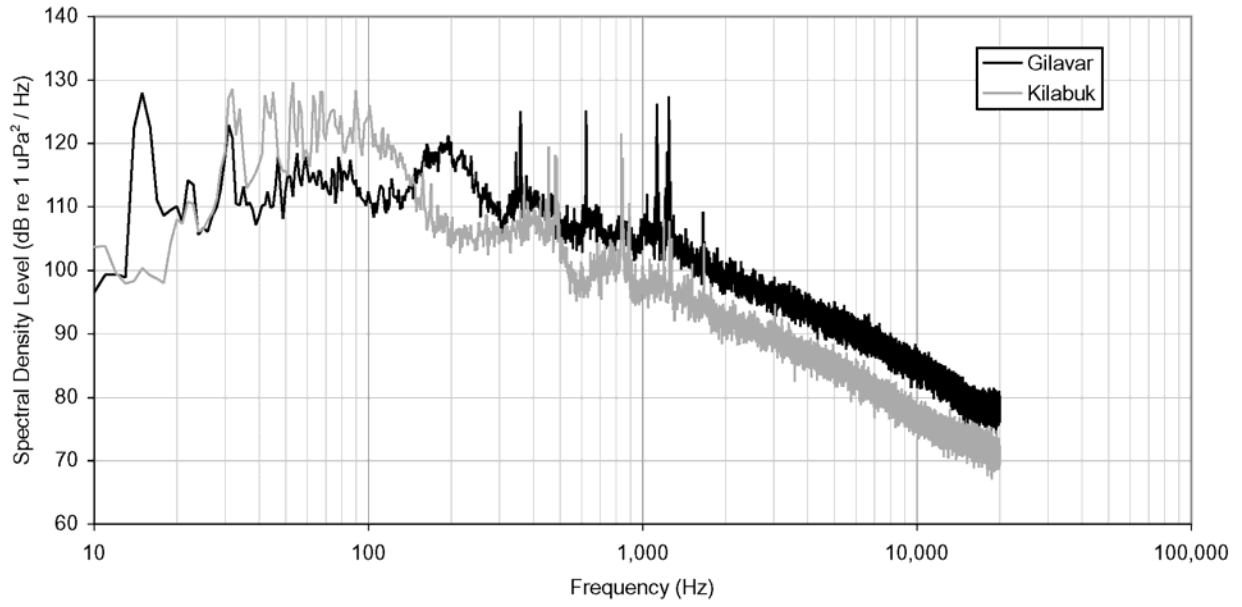

FIGURE 4.29. Spectral density levels of sounds from the *Gilavar* (black line) and the *Kilabuk* (gray line). For each vessel a 10 s sample was analyzed, taken at each vessel's closest point of approach to ASAR #2. FFT size was 44,100 samples, resulting in a 1 Hz bin width.

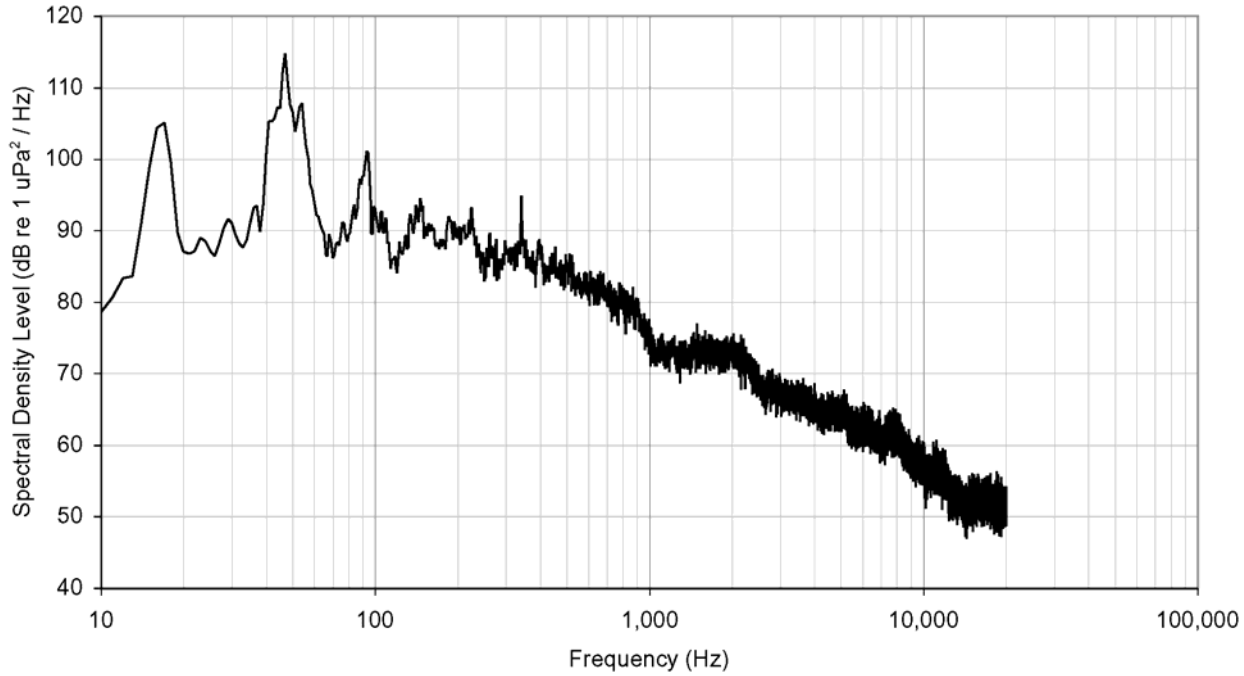

FIGURE 4.30. Spectral density levels of sounds from the *Henry Christoffersen*. A 10 s sample was analyzed, taken while the *Henry C.* was about 310 m from ASAR #2. FFT size was 44,100 samples, resulting in a 1 Hz bin width.

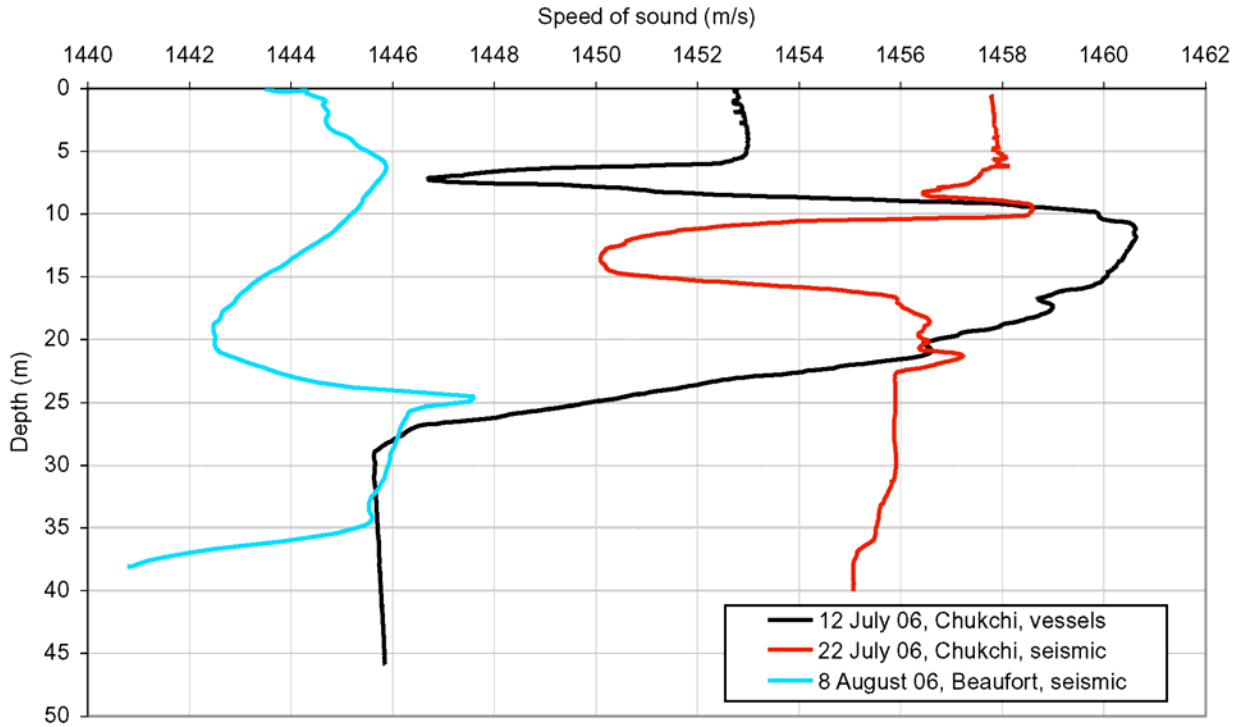

FIGURE 4.31. Sound speed profiles for three sampling locations in the Chukchi and Beaufort Seas (see text).

DISCUSSION

Seismic Sound Measurements

Airgun Pulse Properties

Figures 4.9 and 4.12 show that aspect dependence in the Chukchi Sea measurements was stronger for data collected with the one-string versus the three-string array. This was to be expected since, with the one-string array, there was only one "layer" of airguns (as opposed to three with three strings) and therefore no canceling between pulses traveling different distances to the receiver. This effect was predicted in quantitative terms in JASCO's pre-season modeling of the expected sound fields around the 1-string vs. 3-string arrays. With the one-string array, the highest values for all three level parameters—peak, SPL, and SEL—were found at broadside aspect. Stern aspect data had the lowest values. In three out of four cases (Table 4.4A) the distances to 190 dB and 180 dB (SEL and SPL) shown for the one-string array were 1.5–2 times greater for broadside data than for stern aspect data.

The broadside "face" of the airgun array does not change significantly as parallel strings are added, but the bow and stern "faces" significantly increase with the addition of parallel strings. Thus broadside values for the one-string vs. three-string arrays should be more similar than would be the stern or bow values for one-string vs. three-string arrays. A comparison of received levels (SPL, peak, SEL) at 1 km, as presented in Fig. 4.9 and 4.12, shows that bow and stern values are 7.2–7.8 dB lower for the one-string array compared to the three-string array, but broadside values are only 0.2–0.6 dB lower for the one-string array.

Received levels for all airgun pulse parameters were significantly lower for measurements made in the Beaufort Sea. The airgun cluster towed by the *Henry Christoffersen* included only 4 airguns with a total volume of 280 in^3, compared to 8 airguns totaling 1049 in^3 (one-string array) and 24 airguns totaling 3147 in^3 (three-string array) for the *Gilavar*. All else being equal, the amplitude of the pulses emitted by an array of airguns is proportional to the number of airguns and to the cube root of the total airgun volume (Caldwell and Dragoset 2000). Thus the pressure amplitude should be reduced by 83% (or 15.6 dB), between the *Gilavar*'s three-string (24 gun) array and the *Henry Christoffersen*'s four-gun cluster. The reduction in total gun volume from 3147 in^3 to 280 in^3 is expected to cause a further 45% reduction in amplitude (i.e., a further 7 dB). This adds up to an expected drop of ~23 dB between the *Gilavar*'s three-string array and the *Henry C.*'s four-gun cluster. In actuality, measured peak, SPL, and SEL values for the *Henry C.* were 16–20 dB lower than those for the *Gilavar* at 1000 m from the source, and 24–31 dB lower 10,000 m from the source.

Empirical Versus Predicted Radii

Table 4.4 shows that the difference between measured and predicted radii, as expressed by the E:P ratio, was generally smaller for SPLs than for SELs in the Chukchi Sea dataset. For SPLs the E:P ratios ranged between 0.7 and 4.7 (median = 4.1 and 2.9 for three-string and one-string arrays, respectively), whereas for SELs the E:P ratios ranged between 1.4 and 8.7 (median = 1.7 and 1.5 for three-string and one-string arrays, respectively). Since JASCO's MONM model generates SEL contours from which SPLs are calculated, this seems to indicate that there are variables that are either unknown and therefore not included in the model or that some variables have not been completely taken into account in the model. Differences in environmental conditions between the locations assumed in the model runs as compared with conditions at the ice-free locations where the empirical data were acquired presumably contributed to the deviations between empirical and predicted values. The sound speed profiles collected at the ASAR sites (see Fig. 4.31) are somewhat different than those used in the MONM model; however these differences would probably only contribute to discrepancies at distances larger than the ones of concern for the safety radii.

Differences in bottom properties at the ASAR vs. modeling sites, to the extent they existed, could have had an important effect on the predictions given the shallow water depth. Shallow depths normally cause strong dependence of propagation loss on the local bottom properties. Also, Figure 4.13 shows that the relationship between SPL, SEL, and distance from the sound source may be more complicated than assumed in converting JASCO's model output (in SEL) into the SPL values needed for mitigation purposes (see Chapter 3). Pulse duration and the SEL-to-SPL relationship depended on range, which was expected, but there also were nonlinearities in the way pulse durations increased with range.

Relationship Between SPL, SEL, and Source Distance

Sound exposure levels (SEL) do not depend on the duration of a pulse. Therefore SEL is the measure that is the least susceptible to variability from shot-to-shot, local propagation effects on pulse duration, and background noise. There is general agreement (Madsen 2005; Southall et al. submitted) that SEL is a better measure of an animal's exposure to pulsed or transient sound than is the commonly used SPL. In the dataset from the Chukchi Sea presented in this chapter, pulse-to-pulse variability was unusually low for all parameters (peak, SPL, SEL), but this was most likely due to homogenous physical conditions (i.e., water depth, bottom composition) in the recording area. Another advantage of SELs over SPLs is that a measure of cumulative sound exposure can be calculated when an animal is subjected to a sequence of short transient sounds (e.g., airgun or pile driving pulses) over extended time periods (see for example Madsen et al. 2006).

Despite the increasing popularity of SEL as a metric for reporting impulsive noise, current mitigation requirements and "take" criteria for noise transients, as applied in the U.S., are still based on the SPL metric. This includes the 180 and 190 dB re 1 μPa SPL safety radii for cetaceans and pinnipeds, respectively, and the 160 and 120 dB SPL disturbance criteria used in some situations. It is therefore important to understand the relationship between SPL, SEL, and distance from the sound source. Unfortunately most investigators have not reported their data in such a way as to allow comparisons with Figure 4.13. However, a few other studies provide relevant information as a function of distance from source:

- Greene and Burgess (2000, Fig. 3.5D) present SPLs and SELs for data collected in the Beaufort Sea in 23–26 m deep water and with a 5-m airgun tow depth. The difference between SPL and SEL was ~12 dB at 300 m range and ~5 dB at 6 km. In the Chukchi Sea we measured generally comparable differences, 10–12 dB at 300 m and 1–2 dB at 6 km (Fig. 4.13). Greene and Burgess (2000) did not make measurements at distances large enough for the SEL and SPL to assume equal numeric values.
- Austin et al. (2006), in a preliminary account of sound source verification measurements in the Chukchi Sea for GX Technology Corp., reported SPL–SEL differences of ~7 dB at 300 m and ~1.6 dB at 2.5 km. They made measurements to distances of over 50 km. Unlike the data we present in Fig. 4.13, there was no clear "cross-over" in their data (*cf.* Fig. 7 in Austin et al. 2006), where SEL values consistently exceeded SPL values. Instead their SPL and SEL values converged at ~3–9 km and then diverged out to the farthest measurement distance, with SEL values remaining on average smaller than SPL values. This suggests that, in their dataset, pulse durations did not exceed ~0.9 sec.
- Turner et al. (2006) is a preliminary report on similar measurements in the Chukchi Sea for ConocoPhillips. At ~300 m, SPL and SEL differed by ~10 dB and at 6 km by ~2 dB; this is nearly identical to results of Greene and Burgess (2000) from the Beaufort Sea. Beyond ~10 km in the data of Turner et al., SPL and SEL values were similar.

The results from these studies in the Chukchi and Beaufort seas indicate that the relationship between SPL, SEL, and distance from the sound source is not constant (e.g., see Fig. 4.6 vs. 4.16). It probably depends on the complex interaction between source spectrum and the dispersion characteristics of the propagation environment. A future regulatory focus on SEL rather than SPL would avoid many of the uncertainties involved with pulse durations and their effect on SPL-based safety radii. However, judging from the results of the present study, it will also be important to have an improved way of predicting SEL values for airgun arrays in advance of seismic projects: At least for the Chukchi Sea, the procedure used in 2006 under-predicted the SEL values and associated distances more seriously than it under-predicted the SPL values (Table 4.4).

Effects of M-weighting on Mitigation Results

The results presented in Figure 4.14 make it clear that *M*-weighting, as recommended by Miller et al. (2005) and Southall et al. (submitted), will affect the size of the 180 dB and 190 dB safety radii around an airgun array for certain species of marine mammals.

- For ***baleen whales*** such as bowhead and gray whales, with (presumed) good low-frequency hearing, weighting the received-level data will not change the size of safety radii appreciably. M_{lf}-weighted and unweighted SPL and SEL values are virtually the same (Fig. 4.14).

- For ***pinnipeds*** underwater, the M_{pw}-weighted 190 dB safety radius could shrink to roughly half of its unweighted value. However, the use of a 190- rather than 180-dB safety criterion for seals is at least in part in recognition of their reduced auditory sensitivity to low-frequency sound as compared to baleen whales. If M_{pw}-weighting is to be applied in deriving safety radii for seals, then it may be appropriate to use the M_{pw}-weighted 180 dB (not 190 dB) radius as the safety criterion for seals. The M_{pw}-weighted 180-dB radius is 168% of the unweighted 190-dB radii that are now used as the safety ranges for pinnipeds.

- For ***mid-frequency cetaceans*** such as beluga whales, the M_{mf}-weighted 180 dB safety radius would shrink to a third of its unweighted value.

Most power-downs and shut-downs of airguns during seismic production operations in the Chukchi and Beaufort seas are the result of ringed seal observations by the marine mammal observers (see Chapter 6). Therefore, taking *M*-weighting into account should lead to fewer such interruptions of seismic operations if the safety criterion is the M_{pw}-weighted 190 dB radius. If the safety criterion for seals were defined as the M_{pw}-weighted 180 dB radius, then the number of interruptions would actually increase.

Vessel Sound Measurements

Broadband (10–20,000 Hz) sound levels produced by the *Henry Christoffersen* in the Beaufort Sea were somewhat lower than those produced by the *Gilavar* and *Jim Kilabuk* in the Chukchi Sea. For both the *Gilavar* and *Kilabuk* the highest recorded broadband level was about 145 dB re 1 μPa at distances of ~200–300 m and broadband levels at 1000 m were between 120 and 130 dB. The highest level for the *Henry C.* was 122 dB at ~500 m and the value at 1000 m was ~117 dB re 1 μPa. Figure 3.19 in Greene and Burgess (2000) shows broadband levels as a function of range for four different ships (*Arctic Star, Western Endeavor*, *Saber Tooth,* and *Peregrine*) performing different activities in the Beaufort Sea or recorded over consecutive years. Overall, values for the *Henry Christoffersen* fall in the center of the cloud of points shown in the Greene and Burgess (2000) Figure, and the *Gilavar* and *Kilabuk* fall on the upper edge of that

cloud of points. The small landing craft *Peregrine*, which was also used during the 2006 seismic work described in this report (see Appendix D), was particularly quiet with broadband levels of ~111 dB and 95 dB re 1 μPa at distances of 200 m and 1000 m, respectively.

One noticeable difference between the *Gilavar* and *Kilabuk* data sets is the range at which "background" levels were reached, which was much shorter for the *Kilabuk* (~2 km) than the *Gilavar* (>10 km, see Fig. 4.24–4.26). This was due to different background levels rather than a difference in vessel broadband levels. The difference in background levels did not appear to correlate with changes in sea state; visual observations detected no obvious difference in sea state during the 2.25 hours separating the onset of each vessels' run. During the *Kilabuk* measurements the *Gilavar* was idling 5.6 km from the ASAR locations, whereas during the *Gilavar* measurements the *Kilabuk* was idling 9.3 km from the ASAR locations. However, it is unlikely that the idling *Gilavar* contributed noticeably to the background levels during the *Kilabuk*'s run, since during the zigzag portion of the *Gilavar*'s run, at distances of 0.3–1 km from the ASARs, minimum broadband levels were below "background" levels during the *Kilabuk*'s run (see Fig. 4.24, 16:45–17:30). Another possibility is the presence of another vessel within hearing range during the *Kilabuk*'s run, but we have no information on this possibility. Further spectral analyses would be needed to test these hypotheses.

In the mid-eighties, the *Jim Kilabuk* was named the *Canmar Supplier IV*. Greene (1985, 1987, also presented in Richardson et al. 1995) made recordings of broadband (20–1000 Hz) levels produced by the *Canmar Supplier IV*: ~147 dB at ~200 m, ~135 dB at ~1 km, and ~128 dB at ~10 km. These levels are noticeably higher than the ones presented for the *Kilabuk* in this report, and are also higher than any of the values reported in Figure 3.19 in Greene and Burgess (2000).

SUMMARY

During July through most of September 2006, Shell Offshore Inc. (SOI) conducted 3D/2D seismic surveys in the Chukchi Sea. During August through early October SOI conducted shallow-hazards surveys in the Beaufort Sea. Both types of surveys relied on the generation of underwater acoustic pulses. Greeneridge Sciences, Inc., measured the underwater sound levels produced by the vessels involved, including both seismic and support vessels, and by the acoustic equipment that was used, including airguns and shallow-hazards sources.

Before the onset of field work, JASCO Research Ltd. had estimated, by numerical modeling, the distances from the airgun arrays at which the broadband (rms) received levels would be 190 dB, 180 dB, 170 dB, 160 dB, and 120 dB re 1 μPa. Values measured by Greeneridge were compared to the values that had been predicted by modeling, and were used to recommend updated mitigation radii for use by marine mammal observers on the seismic and shallow hazards ships during data acquisition.

This chapter reports on data collected during two separate field trips involving three different vessels. The seismic ship MV *Gilavar* and the chase vessel MV *Jim Kilabuk* were used in the Chukchi Sea for seismic data acquisition, and the tug and shallow-hazards survey vessel MV *Henry Christoffersen* was used in the Beaufort Sea for acquisition of shallow-hazards data.

Airgun pulses were analyzed at distances of 0.3–34 km in the Chukchi Sea and 0.06–20.5 km in the Beaufort Sea. Logarithmic sound propagation models were fitted to pulse sound pressure levels (SPL), sound exposure levels (SEL), and peak levels. A three-string array (24 airguns totaling 3147 in^3) used in the Chukchi Sea produced the highest values but showed little aspect dependence. A one-string array (8 airguns totaling 1049 in^3) used in the Chukchi Sea showed stronger aspect dependence, with the broadside aspect producing the highest values. Received levels produced by the small airgun array used in the Beaufort Sea

(4 airguns totaling 280 in^3) were generally ~15–30 dB lower (depending on distance from the source) than those in the Chukchi Sea, mainly because the Beaufort Sea array was considerably smaller.

A comparison of empirical vs. modeled SPL values showed that the empirical distances exceeded predicted distances in most (but not all) situations. For the *three-string array,* the E:P (Empirical:Predicted) ratios ranged from 1.2× to 2.0× for the 160 dB, 180 dB, and 190 dB distances, depending on aspect. E:P ratios for the 120 dB distance were higher: 2.6× to 3.2× (considering only bow and stern aspect). For the *single-string array*, E:P ratios were somewhat higher for the 190 dB and 120 dB distances than for the 160–180 dB distances, but in some cases the empirical distances were in fact less than the predicted distances (E:P < 1.0). The E:P ratios for the airgun array used in the Beaufort Sea were in general lower (better) than those obtained in the Chukchi Sea.

A subset of pulses from the Chukchi Sea were *M*-weighted to assess the effect of *M*-weighting on the 190 dB and 180 dB mitigation radii. Three types of *M*-weighting functions were used, those for mid-frequency cetaceans (M_{mf}, e.g. beluga whales), pinnipeds in water (M_{pw}, e.g. ringed seals or walruses), and low-frequency cetaceans (M_{lf}, e.g. bowhead whales). M_{lf}-weighting had virtually no effect on mitigation radii as it barely affected received SPL, SEL, and peak levels. M_{mf}-weighting decreased the 180 dB and 190 dB mitigation radii by about two thirds. M_{pw}-weighting decreased the same mitigation radii by about a half. Since most shut-downs during production are due to the presence of ringed seals, using *M*-weighted data could decrease the number of shut-downs during production if the *M*-weighted 190 dB ratios were used as the safety radius.

Broadband (10–20,000 Hz) levels of vessel sound were analyzed as a function of distance from the sound source. Received levels at 500 m distance were 125–132 dB re 1 μPa for the seismic ship *Gilavar,* and 127–135 dB for the chase vessel *Jim Kilabuk*, depending on aspect (bow, stern, broadside). Both of these ships were recorded in the Chukchi Sea. In the Beaufort Sea, the received broadband level for the tug *Henry Christoffersen* at 500 m distance was ~122 dB re 1 μPa.

ACKNOWLEDGEMENTS

We wish to thank the captains and crews of the *Gilavar*, the *Jim Kilabuk*, and the *Henry Christoffersen* for their support in making these measurements. We could not have obtained any of these data without them. A special thanks to Chris Rollings (chief positioning specialist on the *Gilavar*) for providing the position data for the *Gilavar*. We also thank Michael Schlegel and his team (Geo LLC) for help and advice during the sound measurements from the *Henry C.* Dr. Bill Burgess (Greeneridge Sciences) reviewed the report and provided many useful comments. Dr. Dale Funk and Bob Rodrigues (LGL Alaska) also provided comments on a draft.

ANNEX 4.1: PRELIMINARY MEASUREMENTS OF *GILAVAR* AIRGUN SOUNDS

FIELD REPORT FOR VALIDATION MEASUREMENTS OF SOUNDS PRODUCED BY AIRGUNS ON *M/V GILAVAR* IN THE CHUKCHI SEA ON 21 JULY 2006

Prepared by Susanna B. Blackwell

susanna@greeneridge.com

Revised 6 August 2006[9]

On 21 July 2006 (at ~10:15 local time) two Autonomous Seafloor Acoustic Recorders model B (ASAR-Bs) were deployed on the seafloor ~200 m apart, close to the location 69º 35.85' N, 166º 0.0'W (water depth = 42 m). The recorders have a maximum recording time of about 13 hours at a 44.1 kHz sampling rate, so to maximize recording time their start times were offset. ASAR #2 started recording at 11:00 and ASAR #1 started recording 6 hours later, at 17:00. Between 11:00 on 21 July and 6:00 on 22 July the *M/V Gilavar* followed a course more than 125 km in length designed to provide information on airgun sounds at various distances (~200 m to nearly 35 km), different aspects (bow, stern, and broadside to the vessel) and for two array configurations (one-string and three-string).

Both ASARs were retrieved at ~6:15 on 22 July and 16 GB of acoustic data were downloaded to a laptop computer. Both recorders performed as expected.

The *Gilavar* provided us with time and location information for most of the airgun pulses produced during the recordings. A total of >700 pulses were individually selected and analyzed from most parts of the acoustic records. Groups of 10 consecutive pulses were analyzed about every 10 minutes from all tracks. All or most pulses were analyzed during the few hundred meters preceding and following the *Gilavar*'s closest point of approach (to the ASARs) during each pass. Each analyzed pulse was matched with the location information provided. Broadband sound pressure levels (SPL), which are equivalent to rms (root mean square) levels as used by NMFS for mitigation purposes, were determined for each analyzed pulse. These SPL values were plotted as a function of distance and a sound propagation equation of the type

$$\boldsymbol{RL} = a - b*\log(R) - c*R \qquad \text{Eq. I}$$

[9] This revision supersedes the draft of 26 July 2006, in which the distance estimates to 190 dB, 180 dB, 170 dB, and 160 dB were based on a simpler and less appropriate regression approach which did not take scattering and absorption losses into account.

was fitted to the data. ***RL*** is the received level and *R* is the distance (m) from the source. Two separate data sets were analyzed:

(1) Full array configuration (3 strings, 3147 in^3) – most of the data obtained were with the full array configuration. Data were split into three categories: (a) bow aspect (bow of ship oriented towards ASARs); (b) stern aspect (stern of ship and thus airgun array oriented towards ASARs) and broadside aspect (side of ship oriented towards ASARs). A separate regression was done for sound pressure level data for each of those three categories.

(2) Reduced configuration (1 string, 1149 in^3) – this configuration was used during a few hours in early morning on 22 July. Data were insufficient to split into the three aspect categories mentioned above, so a sound propagation equation was fitted to all pulses analyzed regardless of their aspect (the vast majority of the pulses belonged to the stern aspect category).

Values of *a* (intercept, see Eq. I), *b*, and *c* for the obtained equations are shown in Table 1. The scatter plots and regressions themselves are shown in Figure 1 for the three categories of data obtained with the three-string array, and in Figure 2 for data obtained with the one-string array. The equations shown in Table 1 were used to calculate the distances to 190 dB, 180 dB, 170 dB, 160 dB, and 120 dB re 1 μPa. These distances are shown in Table 2 for the three-string array and Table 3 for the one-string array. Each table also shows the radii predicted by sound propagation modeling done by JASCO Research Ltd. prior to the start of the field season, and the ratios between the field measurements and the predicted values.

With the full three-string array configuration (Table 2), the "field : predicted" ratios for the 190 dB, 180 dB, 170 dB, and 160 dB ranges are 1.2 to 1.9, with most being below 1.5, i.e. the measured values exceeded the modeled values, but generally by no more than a factor of 1.5x. The "field : predicted" ratios for the distances to the 120 dB level were higher, 2.4x to 3.3x. However, the empirical estimates shown in Table 2 are the result of extrapolations over 30+ km beyond the farthest measurement distances. A certain amount of uncertainty is therefore associated with these distances and the resulting ratios.

TABLE 1. Values for variables *a*, *b*, and *c* (Eq. I) in the regressions (sound propagation equations) fitted to four different data sets: pulses produced with the full array (3 strings), for three different aspects, and pulses produced with the reduced array (1 string). The multiple-*R* value is also shown for each equation as well as the range of distances over which the measurements were made and the sample size (number of pulses analyzed).

	a	*b*	*c*	*R* value	Range of distances (km)	Sample size
Full array						
- bow	248.74	22.02	0.000345	-0.998	0.2–30	193
- stern	248.17	22.66	0.000192	-0.994	0.2–34	153
- broadside	238.12	18.85	0.000436	-0.993	0.5–33	148
Reduced array	255.54	26.55	0.000132	-0.990	0.2–30	239

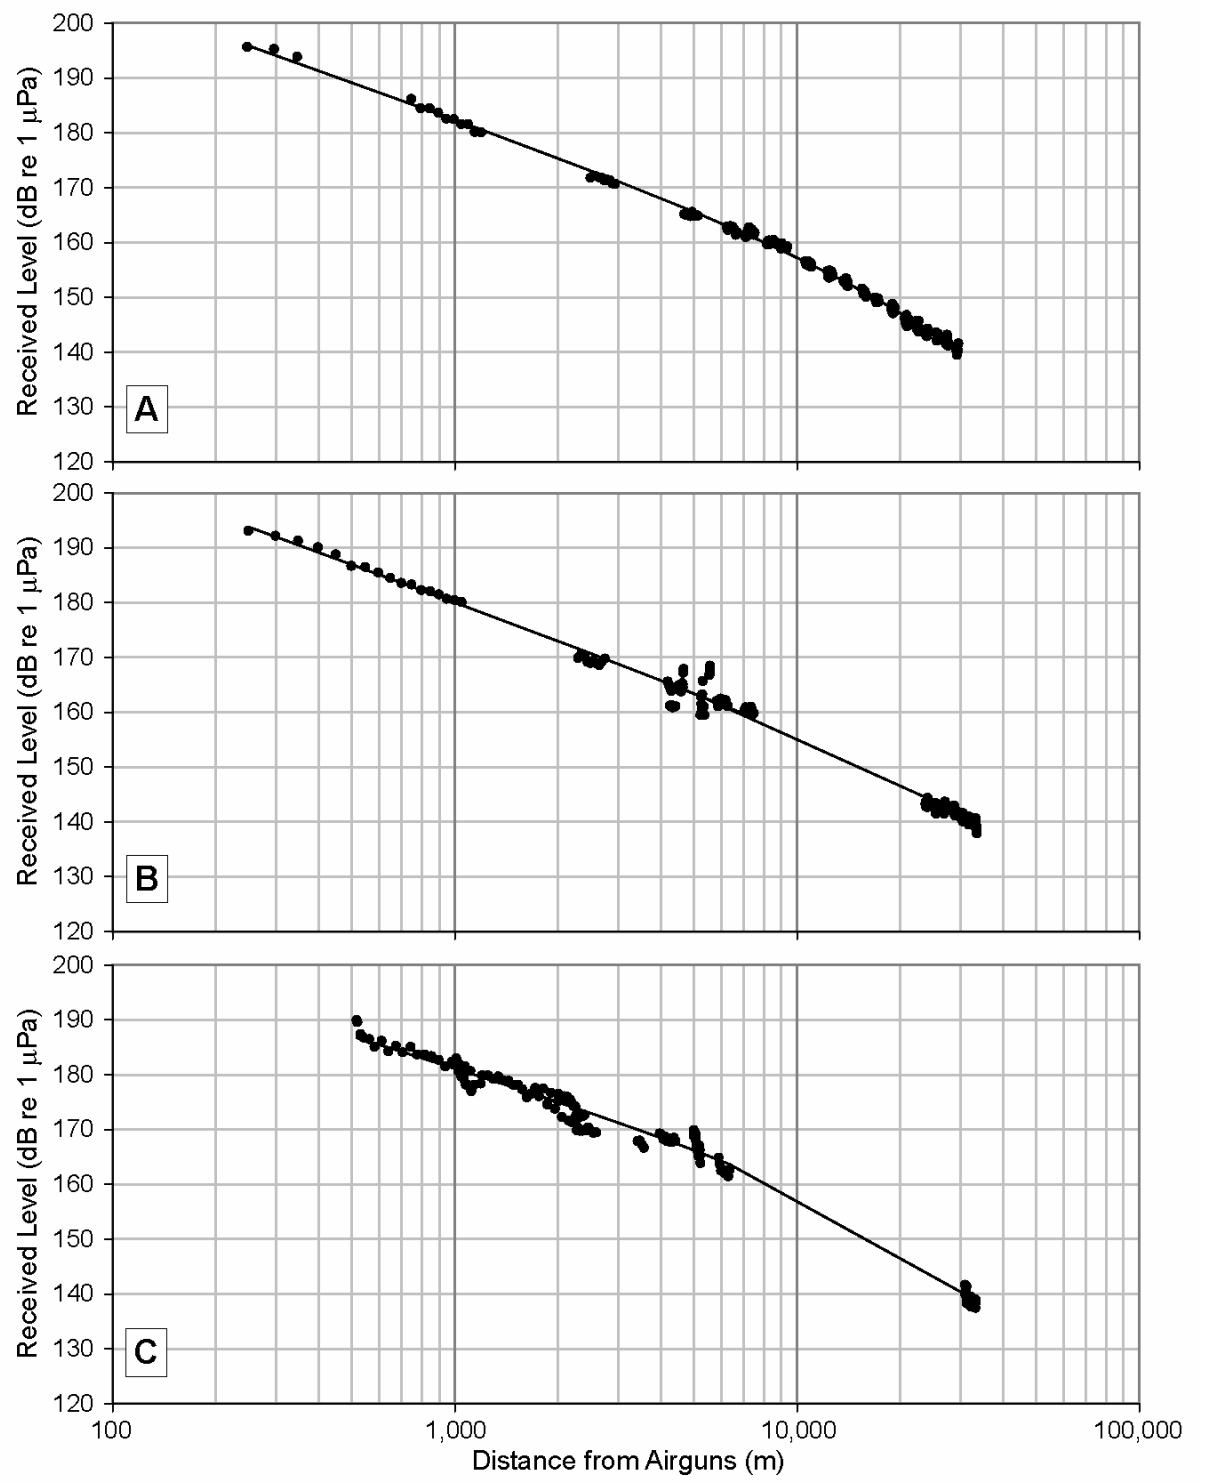

FIGURE 1. SPL values as a function of range for the three-string array. Equations for the lines shown are in Table 1. ***(A)*** Bow aspect; ***(B)*** Stern aspect; ***(C)*** Broadside aspect.

TABLE 2. Distances to specified received SPLs obtained for three-string airgun array, and comparison with modeled values. All distance values are in kilometers. The "field : predicted" ratios were calculated with unrounded distances.

	JASCO predictions	Field measurements			"Field : predicted" ratios		
	C_1, 3147 in^3	Bow	Stern	Broadside	Bow	Stern	Broadside
190 dB	0.23	0.44	0.35	0.33	1.9	1.5	1.4
180 dB	0.81	1.2	0.95	1.1	1.5	1.2	1.3
170 dB	2.19	3.2	2.6	3.3	1.5	1.2	1.5
160 dB	4.53	7.7	6.5	8.4	1.7	1.4	1.9
120 dB	26	65	84	62	2.5	3.3	2.4

TABLE 3. Distances to specified received SPLs obtained for one-string airgun array, and comparison with modeled values. All distance values are in kilometers. The "field : predicted" ratios were calculated with unrounded distances.

	JASCO predictions C_1, 1149 in^3	Field measurements	"Field : predicted" ratios
190 dB	0.26	0.28	1.1
180 dB	0.96	0.67	0.7
170 dB	2.5	1.6	0.6
160 dB	4.7	3.6	0.8
120 dB	35	61	1.7

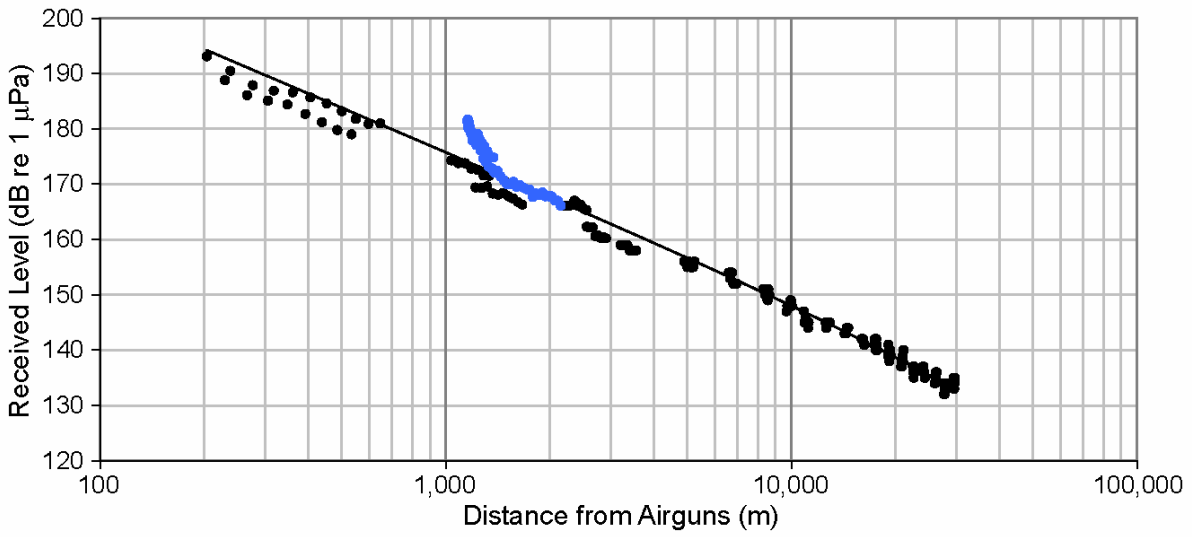

FIGURE 2. SPL values as a function of range for the one-string array. Stern and bow aspect data are shown in black symbols and broadside data are shown in blue symbols. All data were used in calculating the regression. The equation for the line is in Table 1.

There was good agreement between modeled and empirical values for the reduced array configuration (Table 3). The modeled radii for 180 dB, 170 dB, and 160 dB were actually larger than the empirical values, probably because of aspect effects. Most of the empirical data (~85%)

collected with the one-string array fell in the stern aspect category. Broadside data (blue symbols in Fig. 2) were collected during a 2.6 km long southward run ~1.2 km east of the ASARs, with the guns at full volume during the entire run. As the ASARs' latitude was close to the northern end of this run the data became progressively more "stern-like" as the *Gilavar* went south and range increased. For a single-string array aligned parallel to the ship's trackline, we would expect somewhat higher levels at the broadside aspect than from the bow or stern aspects. The empirical data are consistent with this.

Table 4 shows recommended mitigation radii for use by marine mammal observers on the *M/V Gilavar* for both types of arrays. The actual 190 dB, 180 dB, and 160 dB radii will vary depending on aspect (as shown in Table 2) and local conditions. For the ***three-string array*** the maximum of the 3 values (bow, stern, broadside) for each mitigation radius is therefore reasonable as a protective estimate and is shown in Table 4. For the ***one-string array***, the recommended mitigation distance for each criterion is the larger of the empirical or predicted distance (from Table 3). For the one-string array, distances in the cross-track (broadside) direction were not measured. As it is likely that the cross-track distances exceeded those in the along-track direction, the protective approach is to use the predicted distances where these exceed the measured along-track distances.

TABLE 4. Mitigation radii based on empirical data.

	Array size	
	Three-string 3147 in^3	One-string 1149 in^3
190 dB	440 m	280 m
180 dB	1200 m	960 m
160 dB	8.4 km	4.7 km

The actual 120 dB (rms) radius is inevitably more variable than are the radii for the higher received levels, given the longer distances that are involved and the effects of local variations in propagation conditions along those long propagation paths. Also, the necessity to use the fitted regression equations to extrapolate beyond the range of distances with empirical data results in some further uncertainty. Given these considerations, plus the different aspects that were involved, the span of the three estimates for the full 3-string array (62 km to 84 km, Table 2) is relatively narrow.

ANNEX 4.2: PRELIMINARY MEASUREMENTS OF SHALLOW HAZARDS SURVEY SOUNDS

---

16 August 2006

To: Shell International Offshore Inc.
Attn: Mark Kosiara and Michael Macrander

From: Charles Greene, Greeneridge Sciences Inc.

Subject: Measurements of the tug propulsion sounds for *M.V. Henry Christoffersen*, 8 August 2006, Field Report #2

Reference: Measurements of the acoustic sources for the shallow hazard survey by *M.V. Henry Christoffersen*, 8 August 2006, Field Report dated 14 August 2006

Dear Mark and Michael:

This letter presents preliminary results of the measurements of received sound levels vs. distance for propulsion sounds from the tug M.V. Henry Christoffersen to the autonomous seafloor acoustic recorders, model B (ASAR-Bs), not including any survey sound sources. The vessel sounds correspond to survey conditions: only two of four engines, both operating at reduced power and at a speed on the order of 4 knots. The water depth at the recorder installation site was about 48 m and diminished to 37 m at the end of the 20 km course. The starting location was about 54 km east of Kaktovik and the course followed was about 280° T.

The sound level measurements were from the periods between survey pulses and hence represent broadband received levels vs. distance for the tug propulsion sounds. The tug has four engines, each driving a propeller lined up from side to side with two on the outside ("outboard") and two in the middle ("inboard"). The tug was operating on its two outboard engines at reduced power and was making a speed of about 4 knots, suitable for a survey.

This letter is intended for readers who are already familiar with the background and objectives for the measurements. Analyses for this report were for the broadband sounds without frequency analysis.

The letter presents the result of fitting an equation of the form

$$RL \text{ (received level in dB re 1 } \mu\text{Pa rms)} = A - B*\log(R) \quad \text{(for R in meters)}$$

to the measurements. The reference report used an equation with a – C*R term to account for absorption and scattering of the survey sound sources, but the range of distances available here (see below) is inadequate for expecting a rational result for such a term. The equation permits calculating the distances to specific broadband received levels like 120 dB re 1 μPa rms.

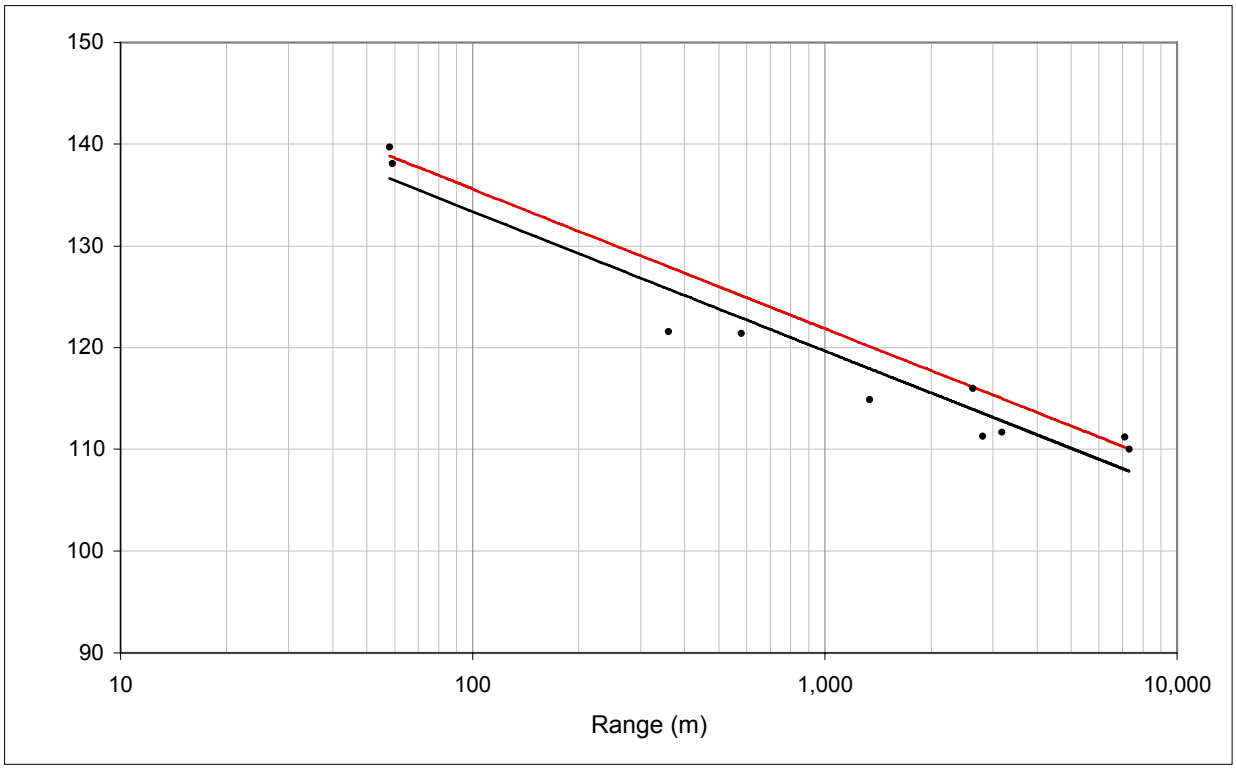
The following Figure shows 10 measured received levels at distances from 58 to 7,320 m. The most distant four measurements, for distances from 12,730 to 20,530 m, were all in the range from 100.1

to 101.4 dB re 1 µPa rms, showing no variation with distance, and are taken to be the background ambient noise level at the measurement site uninfluenced by the tug. They are not plotted. For the 10 remaining values, measured from 58 to 7320 m and resulting in sound pressure levels of 139.7 to 110 dB re 1 µPa rms, the following equation was derived by standard least-squares curve fitting:

RL (received level in dB re 1 µPa rms) = 160.8 – 13.71*log(R) (for R in meters).

The equation results in distances <1 m to 190, 180, and 170 dB and <2 m for the 160 dB received level. The coefficient of determination is 0.9754. The equation results in a distance of 950 m to a received level of 120 dB re 1 µPa rms. This is the distance that would be used in conjunction with an animal density in estimating the number of animals that might have been exposed to a 120-dB sound pressure level.

Because the fitted equation is based on a standard least-squares fit to the measured data, about 50% of the measurements fall above and 50% fall below the fitted curve. Increasing the constant term from 160.8 to 163 results in an equation that exceeds most of the measurement points and predicts a 120 dB (rms) distance of 1370 m. This is the distance beyond which a sound pressure level of 120 dB would not be expected to occur. The following Figure shows the measured data points and the lines corresponding to both the original regression result (lower) and the raised equation (upper).



The 950- and 1370-m distances cited above for the 120 dB contour and monitoring ranges are specifically for the tug operating with survey sources deployed and at slow speed with only two engines each operating at reduced power. For a transiting situation with four engines at normal power and higher speed, longer distances are inevitable. The sound recordings made on 8 August include measurements under those conditions from about 20 km to <100 m but have not been analyzed.

Please call or send email if you have questions about this preliminary material.

Sincerely,

Charles R. Greene

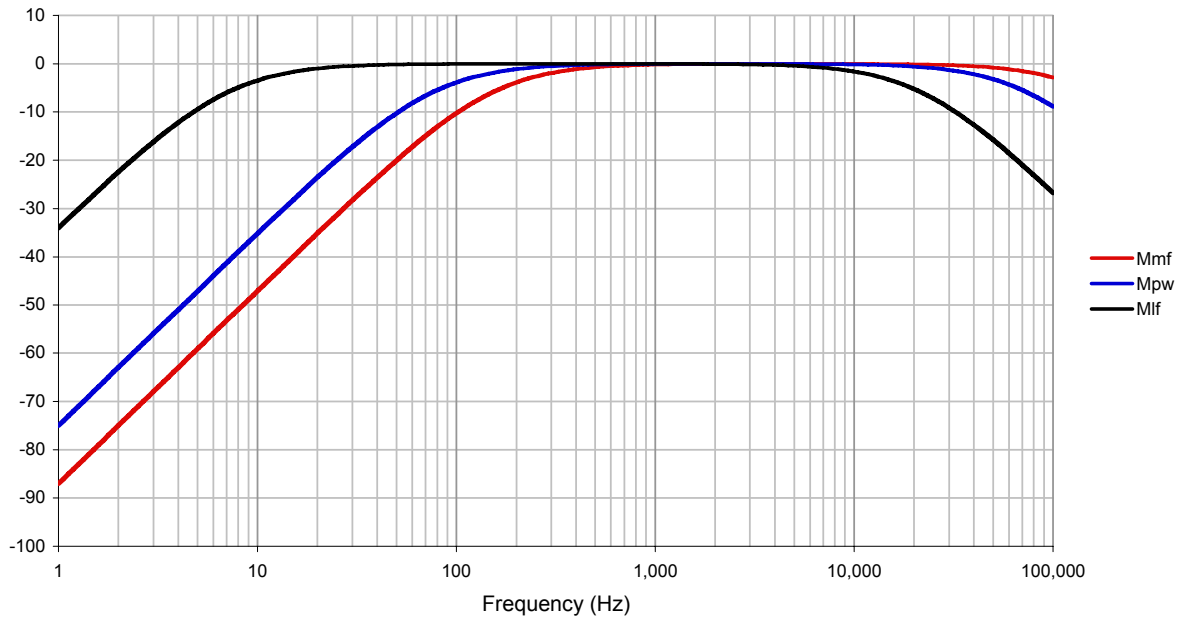
ANNEX 4.3: M-WEIGHTING FUNCTIONS

M-weighting is a filtering algorithm that de-emphasizes frequencies which an animal of concern cannot hear, or hears only weakly. In this report recordings of airgun sounds collected in the Chukchi Sea on 21 July 2006 were *M*-weighted to show the effect of this filtering on received sound pressure levels (SPL) and sound exposure levels (SEL). These results are presented in Figure 4.14. Three different types of *M*-weighting functions were used, one for mid-frequency cetaceans (which include beluga whales), one for pinnipeds in water (seals and walruses), and one for low-frequency cetaceans (bowhead and gray whales). The different *M*-weighting functions are determined by the variables f_{low} and f_{high}, which are conservative estimates of the lower and upper boundaries of effective hearing for each group. F_{low} and f_{high} take on the following values:

- mid-frequency cetaceans (M_{mf}): f_{low} = 150 Hz, f_{high} = 160 kHz;
- pinnipeds in water (M_{pw}): f_{low} = 75 Hz, f_{high} = 75 kHz;
- low-frequency cetaceans (M_{lf}): f_{low} = 7 Hz, f_{high} = 22 kHz;

The Figure below is a graphic representation of the three *M*-weighting functions described above. In this Figure unweighted data would be plotted as a horizontal line at y = 0. Similarly, frequencies between 1 kHz and 3 kHz are untouched by all three weighting functions. The break frequencies (listed above) are the points at which the frequency response has been de-emphasized by 6 dB.



5. MONITORING AND MITIGATION METHODS [10]

This chapter describes the marine mammal monitoring and mitigation measures implemented for SOI's seismic studies in the Chukchi Sea and Shallow hazards survey work in the Beaufort Sea, addressing the requirements specified in the IHAs (Appendices A and B). The section begins with a brief summary of the monitoring tasks relevant to mitigation for marine mammals. A summary of the mitigation measures required by NMFS and USFWS is then presented. The section ends with a description of the vessel-based and aerial survey monitoring and mitigation methods implemented for these surveys and a description of data analysis methods.

Monitoring Tasks

The main purposes of the vessel-based monitoring program were to ensure that the provisions of the IHAs issued to SOI by NMFS and USFWS were satisfied, effects on marine mammals were minimized, and residual effects on animals were documented. Tasks specific to monitoring are listed below (also see Appendix A):

- Provide qualified MMOs for the source and support vessels throughout the seismic surveys in the Chukchi and Beaufort seas.
- Visually monitor the occurrence and behavior of marine mammals near the airguns when the airguns are operating and during a sample of the times when they are not.
- Visually monitor the occurrence and behavior of marine mammals near support vessels when underway.
- Use support vessels to conduct visual surveys of areas where airgun sound could have received levels ≥160 dB re 1 μPa $_{rms}$.
- Record (insofar as possible) the effects of the airgun operations and the resulting sounds on marine mammals.
- Use the visual monitoring data as a basis for implementing the required mitigation measures.
- Estimate the number of marine mammals potentially exposed to strong airgun sounds.

Safety and Potential Disturbance Radii

Chukchi Sea—Gilavar

Under current NMFS guidelines (e.g., NMFS 2000), "safety radii" for marine mammals around airgun arrays are customarily defined as the distances within which received pulse levels are ≥180 dB re 1 μPa (rms) for cetaceans and ≥190 dB re 1 μPa (rms) for pinnipeds. The ≥190 dB re 1 μPa (rms) guideline was also employed by the USFWS for the animals under its jurisdiction (polar bears and walruses) in its IHA issued to SOI. These safety criteria are based on an assumption that seismic pulses at lower received levels will not injure these animals or impair their hearing abilities, but that higher received levels *might* have some such effects. Marine mammals exposed to ≥160 dB (rms) are assumed by NMFS to be potentially subject to behavioral disturbance. However, for certain groups (dolphins,

[10] Chapter 5 by R. Rodrigues, T.A. Thomas, B. Haley and H. Patterson (LGL).

pinnipeds), available data indicate that disturbance is unlikely to occur unless received levels are higher, perhaps ≥170 dB rms for an average animal.

For the current seismic project there has also been concern that received pulse levels as low as 120 dB (rms) may have the potential to disturb some whales. In 2006, there was a requirement to implement special mitigation measures if specified numbers of bowhead cow/calf pairs might be exposed to ≥120 dB rms or if large groups (≥12 individuals) of bowhead or gray whales might be exposed to ≥160 dB rms (MMS 2006). Monitoring of the 160 and 120 dB zones, which was required in the IHA issued by NMFS, is discussed below in the section on Special Mitigation Measures.

SOI's IHA applications described the anticipated underwater sound field around the planned 3147 in^3 airgun array with guns at a depth of 6 m (20 ft). The anticipated acoustic signature for this array was first computed using GSAP, WesternGeco's in-house signature modeling software, and sound output radii for the array were estimated (Table 5.1A).

Subsequent to submitting its applications, SOI contracted with JASCO Research Ltd. to model sound source characteristics using a different model (see Chapter 3). The JASCO implementation of a parabolic equation model was believed by SOI and NMFS to be superior in these waters because it accounts for effects of bathymetry, water properties, and the geoacoustic properties of seabed layers. The radii predicted by JASCO (Table 5.1B) were based on the worst case model predictions. This model was used by SOI to estimate sound level isopleths and radii for received rms sound levels between 120 and 190 dB. These predicted distances were multiplied by a safety margin of 1.5× to obtain initial protective marine mammal safety radii (based on the 190 and 180 dB rms criteria) as well as estimates of "disturbance radii".

Field measurements of the received airgun sounds as a function of distance and aspect were acquired prior to the beginning of routine seismic data acquisition (Blackwell 2006). In all cases involving the primary airgun array (3 strings; total of 24 airguns), measured radii were greater than modeled radii (Table 5.1C). The empirical measurements of the 180 and 190 dB rms radii, as presented by Blackwell (2006), were adopted as safety radii for the survey.

More extensive analysis of the field measurements was completed after the field season, as described in Chapter 4. Those analyses resulted in some refinements of the various radii (Table 5.1D). The refined values were not available for use by the MMOs in the field. However, the refined estimates have been used in Chapter 6 to estimate the numbers of marine mammals exposed to various sound levels.

Airguns operating underwater do not produce strong sounds in air. Accordingly, no shut downs or power downs were implemented for marine mammals on ice. (In any case, none of the sightings of marine mammals on the ice occurred during periods of airgun operation.)

Beaufort Sea—Henry Christoffersen

Sound levels for the equipment on the *Henry Christoffersen* were also modeled by JASCO (see Chapter 3 and Table 5.2A). The actual underwater sounds were recorded as a function of distance on 8 Aug. 2006 in the Beaufort Sea east of Kaktovik, and Table 5.2B,C shows the preliminary and final results of analyses of those data (from Greene 2006 and Chapter 4, respectively). Measured 190, 180, 170 and 160 dB (rms) distances were greater than corresponding predicted distances (Table 5.2). The measured 120 dB distance was less than the predicted distance. The preliminary measurements of the 190 and 180 dB (rms) radii were applied as the safety radii during seismic operations; the final values were used for the analyses in Chapter 6.

TABLE 5.1. Comparison of various predictions and measurements of the 190, 180, 170, 160 and 120 dB rms distances (in km) for sound pulses from the 3-string airgun array deployed from M/V *Gilavar* in the Chukchi Sea, Alaska, 2006.

Received Level (dB re 1 µPa $_{rms}$)	**A.** Radii based on WesternGeco modeling (SOI 2005a,b)	**B.** Radii based on JASCO modeling (Chapter 3)	**C.** Preliminary Measured Radii (Black-well 2006)	**D.** Final Measured Radii (km) (Chapter 4)
190	.120	0.23	0.44	0.46
180	.225	0.81	1.2	1.40

160	0.99	2.22	1.75
120	35.98	24.5	22.2

Mitigation Measures as Implemented

The primary mitigation measures that were implemented during the seismic activities in the Chukchi and Beaufort seas included ramp up, power down, and shut down of the airguns. These measures are standard procedures during seismic cruises and are described in detail in Appendix E. Mitigation also included those measures specifically identified in the IHAs (Appendices A and B) as indicated below.

Standard Mitigation Measures

Standard mitigation measures implemented during the study included the following:

1. Safety radii implemented for the seismic activities were determined based on the preliminary results of the empirical sound measurement studies reported by Blackwell (2006; Table 5.1C) and by Greene (2006; Table 5.2B).
2. Power-down or shut-down procedures were implemented when a marine mammal was sighted within or approaching the applicable safety radius while the airguns were operating. At SOI's request, power-down and shut-down procedures were implemented for pinnipeds sighted within 600 m and 300 m of the *Gilavar*'s operating airguns (i.e., at distances greater than the 190 dB distance from the 3-string array and from a single airgun). This protective measure was in response to the observation of reactions by seals sighted outside the measured 190 dB radius but within 600 m of the airgun array.

3. A change in vessel course and/or speed alteration was identified as a potential mitigation measure if a marine mammal was detected outside the safety radius and, based on its position and motion relative to the ship track, was judged likely to enter the safety radius. In practice, this measure was not implemented because the Gilavar was unable to maneuver while towing the airguns and streamers.
4. A ramp-up procedure was implemented whenever operation of the airguns was initiated.
5. In order for seismic operations to start up during day or night, the full applicable safety radius must have been visible for at least 30 min.

The specific procedures applied during power downs, shut downs, and ramp ups are described in Appendix E. Briefly, a ***power down*** as implemented aboard the *Gilavar* involved reducing the number of operating airguns from the full array of 24 airguns to either one or two airguns when a marine mammal was observed approaching or was seen within the safety radius. Power down also occurred when the *Gilavar* was between seismic survey lines to reduce the area of ensonification. The 190 and 180 dB radii around the much-reduced source operated during a power down were 230 m and 360 m. A ***shut down*** involved suspending operation of all airguns. A shut down was sometimes implemented when a mammal was first sighted within or approaching its safety radius. At other times the airgun array was first powered down, and was later fully shut down if the mammal approached the safety radius around the small source that operated during power downs. A ***ramp-up*** involved a gradual increase in the number of airguns operating, with the number of operating guns generally being doubled every 5 min until the full array was operating.

Special Mitigation Measures as Required by NMFS

In addition to the standard safety radii based on the 190 and 180 dB (rms) distances for pinnipeds and cetaceans, respectively, NMFS (in the IHA) required SOI to monitor the 160 dB radius during all seismic activities. Also, SOI was required to monitor the 120 dB radius after 1 Sept. in the Beaufort Sea and after 25 Sept. in the Chukchi Sea during periods when seismic surveys were occurring. (In the Chukchi Sea, monitoring of the 120 dB zone would have been necessary at an earlier date if 4 migratory bowhead cow/calf pairs were observed during the vessel-based monitoring, or if bowhead whale hunters had determined that cow/calf pairs were passing Barrow in significant numbers.) None of those special criteria were met, so 25 Sept. was the operative date after which monitoring of the 120 dB zone was required in the Chukchi Sea.)

Depending on the results of the monitoring of the 160 dB or 120 dB zones, special mitigation measures were to be implemented:

1. Power-down or shut-down procedures were to be implemented if groups of 12 or more bowhead or gray whales were within the 160 dB (rms) radius while the airguns were in operation.
2. Power-down or shut-down procedures were to be implemented if 4 or more bowhead cow/calf pairs were within the 120 dB (rms) radius after the specified date.

The 160 dB radius was determined by Blackwell (2006) to extend ~8.4 km from the airgun source on the *Gilavar* and was monitored by MMOs onboard the *Kilabuk*. During monitoring of the 160 dB zone the *Kilabuk* followed a zig-zag pattern ~6–8 km ahead of the *Gilavar* (Fig. 5.1). MMOs onboard the *Kilabuk* searched the area ahead of the *Gilavar* within the 160 dB zone for marine mammals. Mitigation (i.e., power down or shut down of the airgun array) was to be implemented if a group of 12 or more bowhead or gray whales entered the 160 dB zone. However, no large groups of baleen whales were observed within the 160 dB zone and no power downs or shut downs were necessary to meet this IHA requirement.

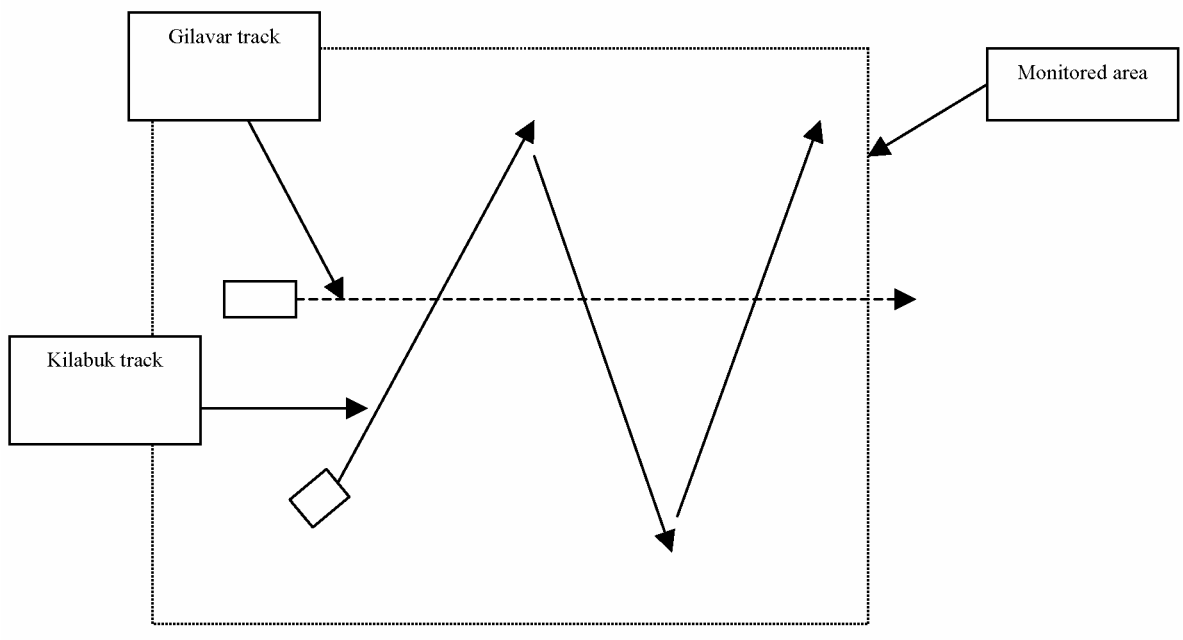

FIGURE 5.1. Diagram of the path of the *Kilabuk* in front of the *Gilavar* during monitoring of the 160 dB zone.

The 120 dB radius was estimated by Blackwell (2006) to extend as much as ~84 km from the *Gilavar,* and the 120 dB mitigation zone covered an area as much as ~22,167 km^2. Monitoring of the 120 dB zone was required at specified times in late summer and autumn due to concerns that seismic noise might disturb bowhead whales, particularly migrating cow/calf pairs, within the 120 dB radius. The IHA allowed for two mechanisms to monitor this large area including (1) the use of survey aircraft to locate cow/calf pairs within the 120 dB radius, and (2) the use of a dedicated passive acoustic monitoring (PAM) system capable of detecting bowhead whale calls within the 120 dB radius. The IHA required that seismic operations be shut down if 4 or more bowhead cow/calf pairs were seen within the 120 dB radius during the aerial monitoring, or if the PAM system detected one or more calling bowhead whales within the 120 dB radius.

In the Chukchi Sea, SOI terminated seismic activities prior to 25 Sept., the date when monitoring of the 120 dB radius was necessary. Therefore, aerial or PAM surveys of the 120 dB zone were not implemented in the Chukchi Sea.

In the Beaufort Sea, 25 Sept. was the one date after 1 Sept. when site clearance activities involving use of airguns were conducted from the *Henry Christoffersen*. An aerial survey was flown on 24 Sept., prior to the beginning of seismic activities, to determine whether bowhead cow/calf pairs were within the 120 dB zone. The aerial survey procedures are described below. No bowhead whales were observed during the survey flight on 24 Sept.

Visual Monitoring Methods

Vessel-Based Monitoring—Chukchi and Beaufort Seas

Visual monitoring methods were designed to meet the requirements identified in the IHAs (see above and Appendices A and B). The primary purposes of MMOs aboard the seismic, shallow hazards, and support vessels were as follows: ***(1)*** Conduct monitoring and implement mitigation measures to

avoid or minimize exposure of cetaceans to airgun sounds with received levels >180 dB re µPa (rms), or of pinnipeds to >190 dB. ***(2)*** Conduct monitoring and implement mitigation measures to avoid or minimize exposure of groups of 12 or more bowhead or gray whales to airgun sounds with received levels >160 dB re µPa (rms). ***(3)*** Document numbers of marine mammals present, any reactions of marine mammals to seismic activities, and whether there was any possible effect on accessibility of marine mammals to subsistence hunters in Alaska. Results of the monitoring effort are presented in Chapter 6.

The visual monitoring methods that were implemented during SOI's seismic exploration were very similar to those used during various previous seismic cruises conducted under IHAs since 2003. The standard visual observation methods are described in Appendix E.

In summary, during the seismic and shallow-hazards surveys in the Chukchi and Beaufort Seas, at least one MMO onboard the source vessel (*Gilavar* or *Henry Christoffersen*) maintained a visual watch for marine mammals during all daylight hours while seismic or shallow-hazards surveys were underway. During the surveys, two visual observer were on duty for 45% of the time watches were conducted on the *Gilavar* and for 2% of the time watches were conducted on the *Henry Christoffersen*. Observers focused their search effort forward of the vessel but also searched aft of the vessel while it was underway. Watches were conducted with the naked eye, Fujinon 7 × 50 reticle binoculars, and Zeiss 20 × 60 binoculars. MMOs instructed seismic operators to power down or shut down the airguns if marine mammals were sighted near or about to enter the appropriate safety radii.

MMOs onboard the *Kilabuk* conducted watches similar to those of MMOs onboard the *Gilavar* and *Henry Christoffersen*. The *Kilabuk* was the chase vessel for the *Gilavar* and generally traveled ~6 to 8 km ahead of the *Gilavar* to monitor the 160 dB radius, which Blackwell (2006) found to extend ~8.4 km from the *Gilavar* sound source. MMOs onboard the *Kilabuk* were thus prepared to notify MMOs onboard the *Gilavar* if groups of bowheads or gray whales (or bowhead cow/calf pairs) were sighted within the 160 dB radius, allowing the *Gilavar* to implement the appropriate mitigation. MMOs aboard the *Gulf Provider* also conducted watches similar to those of MMOs aboard other vessels; these data are not presented in this report but were used in the calculation of densities used to calculate take estimates. Appendix E provides further details regarding visual monitoring methods.

Aerial Surveys—Beaufort Sea

An aerial survey program was conducted in support of the seismic program in the Beaufort Sea during fall of 2006. The objectives of the aerial survey were

- to advise operating vessels as to the presence of marine mammals in the general area of operation;
- to collect and report data on the distribution, numbers, orientation and behavior of marine mammals near the seismic operations with special emphasis on migrating bowhead whales;
- to support regulatory reporting and Inupiat communications related to the estimation of impacts of seismic operations on marine mammals;
- to monitor the accessibility of bowhead whales to Inupiat hunters; and
- to document how far west of seismic activities bowhead whales travel before they return to their normal migration paths, and if possible, to document how far east of seismic operations the deflection begins.

SOI originally intended to conduct aerial surveys in the summer (July to late Aug.) to collect pre-seismic, baseline data although few cetaceans were expected to occur in the project area at that time. Fall

surveys (late Aug. to Oct.) were planned to obtain detailed data (weather permitting) on the occurrence, distribution, and movements of marine mammals, particularly bowhead whales, within about 50 km to the east and 70 km to the west of the primary seismic vessel, and to monitor the 120 dB radius for bowhead whales prior to seismic activities. Logistical problems early in the summer season precluded SOI's ability to conduct summer aerial surveys and the aerial survey program did not begin until 26 Aug.

SOI's seismic source vessel, the *Gilavar*, conducted seismic operations in the Chukchi Sea until late September at which time it was to transit to the Beaufort Sea to continue seismic acquisition within specific lease holdings. However, due to weather and ice conditions, the *Gilavar* terminated its seismic activities in late September and did not conduct deep seismic acquisition in the Beaufort Sea in 2006. SOI's vessel-based activities in the Beaufort Sea were confined to site clearance and shallow hazard surveys in the mid- and eastern Alaskan Beaufort Sea. Consequently, some of the original objectives of the aerial survey program could not be achieved. For example, since the *Gilavar* did not conduct any seismic activities in the Beaufort Sea, it was not possible to document any bowhead deflection away from and subsequent return to their migration path.

Nine aerial surveys were conducted between 26 Aug. and 24 Sept. SOI's only use of airguns in the Beaufort Sea in 2006 occurred on 25 Sept. and was related to site clearance and shallow hazard surveys. Aerial surveys on 23 and 24 Sept. to monitor the 120 dB zone were conducted prior to seismic activities on 25 Sept. Seven other aerial surveys between 26 Aug. and 14 Sept. were conducted to collect data on marine mammal distribution and abundance within the project area prior to any seismic activities. The general location of the aerial surveys and aircraft route are shown on Figure 5.2.

During the aerial surveys 2 primary observers were seated at bubble windows on opposite sides of the aircraft. The two primary observers searched the water visible through the bubble windows with the unaided eye concentrating on the area within 1 km of the aircraft. When a marine mammal was sighted, the observers dictated into a digital recorder the species, number of individuals, size/sex/and age class when determinable, activity, heading, swimming speed category (if traveling), sighting cue, ice conditions (type and percentage), and inclinometer reading. The inclinometer reading was recorded when the animal's location was 90° to the side of the aircraft track, allowing calculation of lateral distance from the aircraft trackline. In addition, each observer recorded the time, sightability (subjectively classified as excellent, good, moderately impaired, seriously impaired or impossible), sea state (Beaufort wind force), ice cover (in 10ths) and sun glare (none, up to 10% glare, 10–30% glare, >30% and <70% glare, and >70% glare) at 2-min intervals along the transect, and at the end of each transect. This provided data in units suitable for statistical summaries and analyses of effects of these variables (and position relative to seismic vessel) on the probability of detecting animals (see Davis et al. 1982; Miller et al. 1999; Thomas et al. 2002).

A third observer's primary duty was to enter data into a laptop computer although this observer also searched for marine mammals during periods when data entry was not necessary. Transect information, sighting locations, and environmental data were entered into a GPS-linked laptop computer by the third observer, and simultaneously recorded on audiotape for backup and validation. At the start of each transect, a designated primary observer recorded the transect start time and position, ceiling height (ft), cloud cover (in 10ths), wind speed (knots), wind direction (°T) and outside air temperature (°C). The laptop computer used Garmin Mapsource (ver 6.9) position logging software. Mapsource automatically stored the time and aircraft position at pre-selected intervals (typically at 6 sec for straight-line transect surveys) to a file as they were obtained. The observer operating the computer recorded a waypoint at the start and end of each transect, at 2-min intervals along the transect line coinciding with the environmental data collected by the primary observers, and when a marine mammal was sighted by any of the observers.

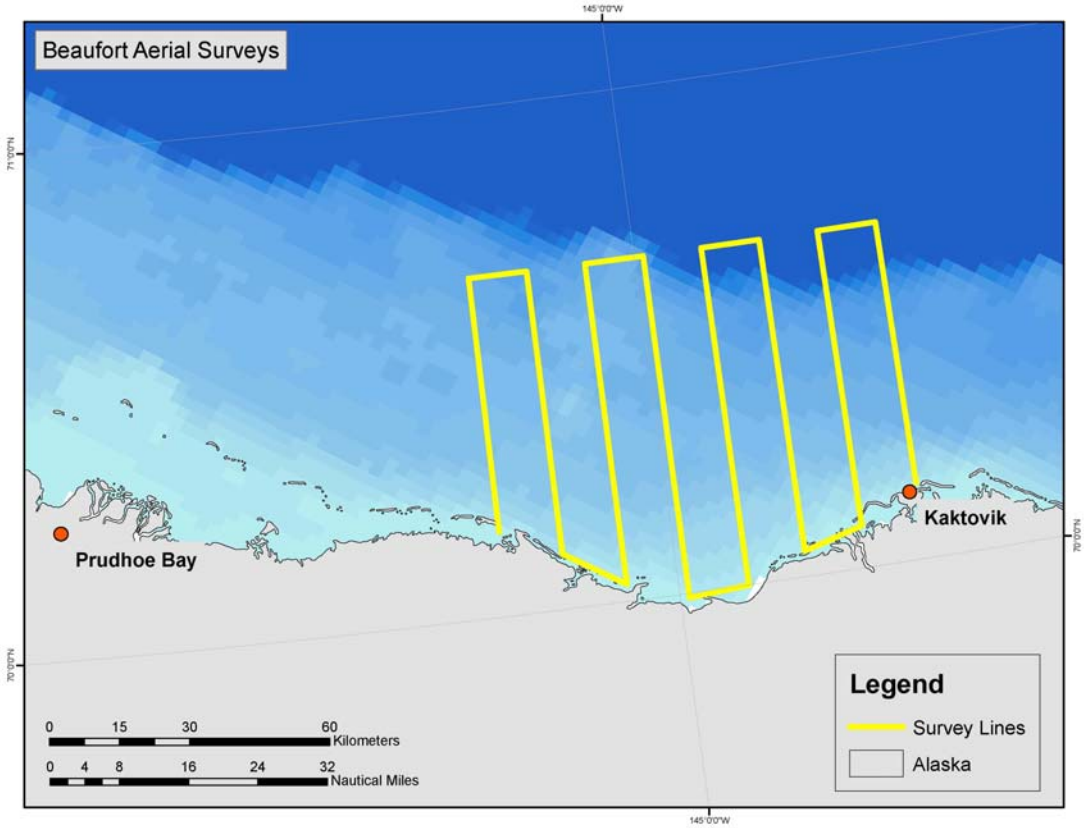

FIGURE 5.2. Approximate locations of transect lines for aerial surveys of marine mammals in Camden Bay, Alaska 2006.

Analyses

Vessel-Based Surveys

Categorization of Data.—Observer effort and marine mammal sightings were divided into several analysis categories related to vessel and seismic activity. The categories were similar to those used during various other recent seismic studies conducted under IHAs (e.g., Haley and Koski 2004; MacLean and Koski 2005; Smultea et al. 2005; Holst et al. 2005a,b; Ireland et al. 2005). These categories are defined briefly below, with a more detailed description provided in Appendix E.

In general, data were categorized as "seismic" or "non-seismic". "Seismic" included all data collected from the source vessel (*Gilavar* or *Henry C.*) while the airguns were operating. Non-seismic included all data obtained before the airguns were activated (pre-seismic) or >1 or >2 h (for pinnipeds and cetaceans, respectively) after the airguns were deactivated. Data collected during post-seismic periods from 3 min to 1 h (for pinnipeds) or 2 h (for cetaceans) after cessation of seismic activity were considered either "recently exposed" (3–30 min) or "potentially exposed" (30 min to 1 or 2 h) to seismic sound levels, and were excluded from analyses. Thus, the post-seismic data (3 min to 1 or 2 h after cessation of seismic) were not included in either the "seismic" or "non-seismic" categories. The 3 min cutpoint was considered appropriate because of the relatively slow speed during seismic operations (~4 kt or 7.4 km/h, average). The 1 and 2 h cutoff periods correspond to the time required to transit to an area in which the received sound level would not be likely to have much (if any) effect on the distributions of pinnipeds and cetaceans, respectively. The chosen sound levels were comparable to those used in other recent seismic

cruises (Haley and Koski 2004; MacLean and Koski 2005; Holst et al. 2005a; Ireland et al. 2005). Periods of time during which other vessels were sighted within 1 km of the *Gilavar* (for pinnipeds) and 5 km of the *Gilavar* (for cetaceans) were also excluded. At the time of publishing it was not possible to calculate the specific distance between the *Kilabuk* and *Gilavar* beyond the usual operating distance of ~3 nm or ~6 km apart. At this distance it is unlikely that the distribution of pinnipeds would have been affected by the seismic noise generated by the *Gilavar*; thus all pinniped sightings from the *Kilabuk* are included as 'non-seismic'. The distance at which the distribution of cetaceans may have been affected by the *Gilavar* was greater; therefore we did not classify cetacean sightings from the *Kilabuk* as either seismic or non-seismic.

This categorization system was designed primarily to distinguish potential differences in behavior and distribution of marine mammals with and without seismic surveys. The rate of recovery toward "normal" during the post-seismic period is uncertain. Marine mammal responses to seismic sound likely diminish with time after the cessation of seismic activity. The end of the post-seismic period was defined as a time long enough after cessation of airgun activity to ensure that any carry-over effects of exposure to sounds from the airguns would have waned to zero or near-zero. The reasoning behind these categories was explained in MacLean and Koski (2005) and Smultea et al. (2005) and is discussed in Appendix E.

Line Transect Estimation of Densities.—Marine mammal sightings during the "seismic" and "non-seismic" periods were used to calculate sighting rates (#/km). Sighting rates were then used to calculate the corresponding densities (#/km^2) of marine mammals near the survey and chase ships during seismic and non-seismic periods. Density calculations were based on line-transect principles (Buckland et al. 2001). Because of assumptions associated with line-transect surveys [sightability, $f(0)$, $g(0)$, etc.], only "useable" effort and sightings were included in density calculations. Effort and sightings were defined as "useable" when made under the following conditions: daylight periods both within the seismic survey area and during transit to and from that area, excluding

- periods 3 min to 1 or 2 h after the airguns were turned off (post-seismic), or
- when ship speed was <3.7 km/h (2 kt), or
- with seriously impaired sightability. (This included all nighttime observations, and daytime periods with one or more of the following: visibility <3.5 km, Beaufort sea state (Bf) >5 (Bf >2 for porpoises), or >60º of severe glare between 90º left and 90º right of the bow.)

When calculating sighting rates and densities in non-seismic periods (for comparison with those in seismic periods), only the observations in the Chukchi Sea were considered, i.e., observations during transit through the Bering Sea were excluded. Pinnipeds hauled out on the ice were encountered in both the Beaufort and Chukchi seas; these sightings were considered "useable" for analyses.

Correction factors for missed animals, i.e., $f(0)$ and $g(0)$, were calculated for gray whales, bowhead whales, unidentified whales, bearded seals, ringed seals, Pacific walruses, unidentified seals, and unidentified pinnipeds (see Appendix E). Other correction factors were taken from other related studies, as summarized by Koski et al. (1998) and Barlow (1999). This was necessary because of the low number of sightings of any individual species, making estimation of $f(0)$ from project specific data problematic, and because of the inability to assess trackline sighting probability, $g(0)$, during a study of this type.

Densities estimated from non-seismic observations were used to estimate the numbers of animals that presumably would have been present in the absence of seismic activities. Densities during seismic periods were used to estimate the numbers of animals present near the seismic operation and exposed to various sound levels. The difference between the two estimates could be taken as an estimate of the number of animals that moved in response to the operating seismic vessel, or that changed their behavior sufficiently to affect their

detectability to visual observers. However, in the case of the *Henry Christoffersen,* because of the very limited duration of airgun operations during this study, the reported densities during seismic periods are not reliable indicators of actual densities during seismic operations. Thus, a comparison of densities observed from the *Henry Christoffersen* during seismic and non-seismic periods is not a valid method for estimating changes in distribution or behavior during this study. Further details on the line transect methodology used during the survey are provided in Appendix D.

Estimating Numbers Potentially Affected.—For purposes of the IHA, NMFS assumes that any marine mammal that might have been exposed to airgun pulses with received sound levels ≥160 dB re 1 µPa (rms) may have been disturbed. When calculating the number of mammals potentially affected, we used the measured 160 dB radii with some adjustments based on JASCO's model for situations where specific measurements were not available (Tables 5.1D, 5.2C).

Two approaches were applied to estimate the numbers of marine mammals that may have been exposed to sound levels ≥160 dB re 1 µPa (rms):

1. Estimates of the numbers of potential *exposures* of marine mammals, and
2. Estimates of the number of different *individual* mammals exposed (one or more times).

The first method ("exposures") involved multiplying the following three values for each airgun configuration in use: (A) km of seismic survey; (B) width of area assumed to be ensonified to ≥160 dB (2 × 160 dB radius); and (C) densities of marine mammals estimated from this study (Appendix I). Thus, areas of water ensonified on more than one occasion, due to overlapping or adjacent tracklines, were counted in the area calculation as many times as they were ensonified.

The second approach ("individuals") involved multiplying the same three values, except that areas ensonified to ≥160 dB on more than one occasion, due to overlapping tracklines, were counted only once. The area of water considered ensonified in this calculation is therefore smaller than in the first calculation. During the Chukchi Sea surveys by the *Gilavar,* many of the tracklines were in close proximity to one another in comparison with the 160 dB distance, leading to much overlap of the areas ensonified to ≥160 dB during transits along the various tracklines. In this situation, the two approaches lead to very different values for the ensonified area, and the estimated number of exposures is much higher than the estimated number of individuals exposed.

The two approaches can be interpreted as providing maximum and minimum (respectively) estimates of the number of marine mammals that would have been exposed to sound levels ≥160 dB re 1 µPa (rms) if they did not show avoidance reactions. The actual number is probably somewhere between these two estimates. This approach was originally developed to estimate numbers of seals potentially affected by seismic surveys in the Alaskan Beaufort Sea conducted under IHAs (Harris et al. 2001). The method has recently been used in estimating numbers of seals and cetaceans potentially affected by other seismic surveys conducted under IHAs (e.g., Haley and Koski 2004; Smultea et al. 2004, 2005; MacLean and Koski 2005; Holst et al. 2005a,b). The methodology is described in detail in these past reports and in Appendix E.

Aerial Surveys

Seismic activities when each aerial survey was flown were determined from data compiled by the marine mammal observers on the seismic source vessels. In 2006, the seismic source vessel (*Henry Christoffersen*) conducted seismic activities on 25 Sept. No aerial surveys were flown on 25 Sept. due to poor weather conditions, but surveys were flown on 23–24 Sept. to monitor the 120 dB zone. Only these

surveys flown on 23–24 Sept. are analyzed in this report. Given the very limited airgun operations in the Beaufort Sea in autumn 2006, there are insufficient 2006 data with which to analyze differences in cetacean distribution with and without seismic activity.

Determination of Estimated Take by Harassment

160 dB Criteria.—NMFS practice in situations with intermittent impulsive sounds like seismic has been to assume that "take by harassment" (Level B) may occur if baleen whales are exposed to received levels of sounds exceeding 160 dB re 1 μPa rms (NMFS 2005b, 2006b). The reaction threshold for most toothed whales is unknown but presumably higher because of their poorer hearing sensitivity at low frequencies (NMFS 2005b; NMFS 2006b; Richardson et al. 1995; Richardson and Würsig 1997). However, the limited empirical data for beluga whales indicate that they may be relatively responsive to airgun sounds as compared with other toothed whales (G. Miller et al. 2005). The monitoring plan for 2006 called for estimates of the numbers of bowhead and beluga whales observed within the 160 dB (and 180 dB) zones, along with other estimates of take described later.

When calculating the number of cetaceans potentially affected, we used the nominal 160 dB (or 180 dB) distances for the situation in which the survey took place (Table 5.1D, 5.2C). As described above, two approaches were applied to estimate the number of exposures of marine mammals to sound levels ≥160 dB re 1 μPa (rms), and the number of different individual marine mammals exposed to such levels. These two approaches can be interpreted as providing maximum and minimum (respectively) estimates of the number of marine mammals that would have been exposed to sound levels ≥160 dB re 1 μPa (rms) if they did not show avoidance reactions.

120 dB Criteria.—Corresponding procedures were used to estimate the numbers of whales that either occurred within or avoided the zones within 24.5 km (Table 5.2B) of the airguns operated by the *Henry C*. The "120 dB criterion" was called for by MMS (2006) and the IHA issued by NMFS because 1996–98 monitoring results showed that most migrating bowheads avoided the areas within 20 km of the operating airgun arrays (Miller et al. 1999; Richardson et al. 1999). During the 1996–98 studies, received levels of airgun pulses at 20 km at times were as low as 120 dB re 1 μPa rms (Burgess and Greene 1999). Shell's IHA (NMFS 2005b, 2006b) required, during operations in the Beaufort Sea after 1 Sept., monitoring areas within the 120 dB distance for bowhead mother/calf pairs.

SOI's seismic operations in the Chukchi Sea terminated on 23 Sept. Because seismic operations in the Chukchi Sea did not occur after 25 Sept., there was no requirement to estimate numbers of cetaceans exposed to ≥120 dB rms in that area.

6. RESULTS OF SHELL'S MARINE MAMMAL MONITORING PROGRAM[11]

INTRODUCTION

This chapter provides background information on the occurrence of marine mammals in the Chukchi and Beaufort Seas, and describes the results of Shell's 2006 marine mammal monitoring program. In addition, the numbers of marine mammals potentially affected during project operations within the two study areas are estimated. The study areas, for the purposes of marine mammal data analyses, were the actual seismic survey areas and transit areas within the Chukchi Sea (see Fig. 2.1, 2.2).

The marine mammals known to occur along the cruise trackline across the Beaufort and Chukchi Seas belong to four taxonomic groups: odontocetes (toothed whales, including the beluga whale), mysticetes (baleen whales), pinnipeds (seals and walruses), and ursids (polar bear). Nine cetacean species and five species of pinnipeds are known to occur along the cruise trackline, along with the polar bear. Of the total 15 species, three (all cetaceans) are listed under the U.S. Endangered Species Act (ESA) as endangered: the bowhead, humpback, and fin whales. Appendix F summarizes the abundance, habitat, and conservation status of the marine mammal species likely to occur in the cruise area.

CHUKCHI SEA MONITORING

Monitoring Effort and Marine Mammal Encounter Results

This section summarizes the visual monitoring effort and sightings from the *Gilavar* and *Kilabuk* during the Chukchi seismic survey from 7 July to 25 Sept. 2006. Summaries of results of visual monitoring are presented here, with more detailed data presented in Appendices G and H, including survey effort in both kilometers and hours. A general summary of effort and sightings is shown in Table 6.1 and Appendix Table G.1. Marine mammals observed during transits outside the study area are summarized in Table G.2.

Seismic survey activities by the *Gilavar* occurred along 9556 km of trackline over a total of 1092 h (Fig. 2.1; Table G.1). In total, 27,585 km and 2788 h of visual observations were conducted within the Chukchi Sea study area, including 13,527 km and 1537 h of observation from the *Gilavar* and 14,058 km and 1251 h from the chase vessel *Kilabuk*. "Useable" survey conditions occurred during 52% (in km; 49% in h) of the total visual effort (Table G.1). "Useable" effort excluded periods 3 min to 1 h (for pinnipeds) or 2 h (for cetaceans) after the airguns were turned off, poor visibility conditions (visibility <3.5 km or extensive glare), and Bf >5. Periods of time during which other vessels were sighted within 1 km of the *Gilavar* (for pinnipeds) and 5 km of the *Gilavar* (for cetaceans) were also excluded. At the time of publishing it was not possible to calculate the specific distance between the *Kilabuk* and *Gilavar* beyond the usual operating distance of ~3 nm or ~6 km apart. At this distance it is unlikely that the distribution of pinnipeds would have been affected by the seismic noise generated by the *Gilavar*; thus all pinniped sightings from the *Kilabuk* are included as 'non-seismic'. The distance at which the distribution of cetaceans may have been affected by the *Gilavar* was greater; therefore we did not classify cetacean sightings from the *Kilabuk* as either seismic or non-seismic. As such, cetacean sightings from the *Kilabuk* are described but *not* included in any analyses

[11] By Heather Patterson, Tannis Thomas, Andrea Hunter, Meaghan Jankowski, Beth Haley, and Ross Harris (LGL).

[a] Useable sightings are those made during useable daylight periods of visual observation, as defined in *Acronyms and Abbreviations*.

[b] Includes the "Post-Seismic" category.

or calculations. The project provided data on the summer occurrence, distribution, and abundance of marine mammals in the Chukchi Sea, an area where few systematic survey data had been collected previously.

Visual Survey Effort

Survey effort from the *Gilavar* and *Kilabuk,* in km and h, subdivided by seismic activity and Beaufort wind force, is summarized in Table G.1.

Gilavar.—During 13,527 km of *Gilavar* observations during the cruise, 4214 km of useable visual observations were made (Table G.1). MMOs observed almost exclusively from the bridge (99% of watch time, eye-height 10.8 m), with the remaining observations conducted from the flying bridge or stern (0.5% each). Of the 1537 h and 13,527 km of visual observation effort, 18 h and 156 km occurred during nighttime ramp up and the preceding half hour before the airguns were on. One observer was on visual watch aboard the *Gilavar* during 901 h (8626 km), with at least two observers on watch during the remaining 731 h (6636 km).

Kilabuk.—Within the Chukchi Sea, the MMOs aboard the *Kilabuk* observed over a distance of 14,058 km, with useable visual observations occurring during 13,377 km (Table G.1). Useable survey effort is shown in Table G.1. All visual observations from the *Kilabuk* were made from the bridge and during daytime. One observer was on visual watch aboard the *Kilabuk* during 1313 h (15,381 km), with at least two observers on watch during the remaining 28 h (497 km).

Beaufort Wind Force (sea state) during observations aboard the *Gilavar* and *Kilabuk* ranged from 0 to 8 within the Chukchi Sea, with 0.6% (in h) of the observation effort during conditions of Bf = 0 (Table G.1). The majority (65%) of the 2788 h of observation effort occurred with Beaufort Force 3 to 5 (wind speed 7–21 kt or 13–39 km/h). This is typical for the summer in the study region (Pilot Chart, date unkn.).

Visual Sightings of Marine Mammals and Other Vessels

Numbers of Marine Mammals Seen.—An estimated 674 individual marine mammals were seen in 480 groups through the Chukchi sea study area (Table 6.2). Twelve different marine mammal species were identified, with the gray whale being the most commonly identified (n = 117 individuals in 53 groups), followed by Pacific walruses (n = 104 in 36 groups; Table 6.3). In addition, 13 groups (34 individuals) of bowhead whales, 5 groups (5 individuals) of minke whales, and 10 groups (12 individuals) of bearded seals were identified. Of the 51 seals identified in the study area, 28 (or 55%) were ringed seals. Other seal species that were identified were spotted seals (20 individuals), bearded seals (15) and ribbon seal (1). There were many sightings of unidentified seals (n = 273 individuals in 258 groups); most of these were likely ringed seals, given the visual monitoring results and the known occurrence of this species throughout the study area.

The number of cetacean groups seen from the *Kilabuk* (n = 35) was less than half the number seen from the *Gilavar* (n = 80; see Tables ES.1 and 6.3. Pinniped sightings from the *Gilavar* were also more numerous than from the *Kilabuk* (n= 204 and 161, respectively), with 16 and 20 of these sightings being confirmed as Pacific walruses. A detailed list of sightings is provided in Table G.3.

Most of the 480 sightings (65% or 311 groups) made within the study area were "useable" (Table 6.2, 6.3). These "useable" sightings, along with the corresponding effort data, are the basis for the ensuing analyses comparing sighting rates and behaviors of marine mammals during seismic and non-seismic periods.

No deaths or injury of animals was observed during the seismic program. Numerous carcasses of whales, seals, and walruses were sighted; these are included in the summary of marine mammal sightings

TABLE 6.2. Numbers of sightings and of individual marine mammals, both (A) total, and (B) useable[a], observed in the study area from the Gilavar (10 Jul.−23 Sept. 2006) and from the Kilabuk (10 Jul.−4 Oct. 2006), during the Chukchi Sea cruise.

[a] Useable sightings are those made during useable daylight periods of visual observation, as defined in *Acronyms and Abbreviations*.

(Table G.3). Where feasible, which was the majority of cases, carcasses were approached to closer range by the *Kilabuk*, observed in detail, and photographed by the MMOs. Most carcasses showed signs of advanced decomposition. The exceptions to this were walrus carcasses that were headless and undoubtedly taken by hunters.

Sightings with Airguns On.—Of the total 480 sightings, 102 were made while the airguns were operating, 356 were made during non-seismic periods, and the remaining 22 were noted during "post-seismic" periods (Tables ES.1, 6.2).

Power downs were requested on 10 occasions and shut downs were requested on 38 occasions when pinnipeds or cetaceans were sighted in the water within the 190 dB or 180 dB (rms) safety radii

(respectively) around the operating airguns. Further details on these encounters are provided later in this chapter (see *Mitigation Measures Implemented*) and in Appendix H.

Sighting Rates.—Sighting rates (# groups sighted per unit effort) during various types of MMO effort are presented in Table 6.1. Sighting rates for all types of marine mammals were higher from the *Gilavar* than the *Kilabuk*. This is not surprising given that observers on the *Gilavar* stood at a greater height above the water.

Based on the number of groups seen per kilometer, sighting rates were generally higher during non-seismic operations than during seismic conditions (Table 6.1). This is true regardless of whether the *Kilabuk* sightings are included. For cetaceans, the sighting rate from the *Gilavar* was only 0.5 detections/1000 km during seismic periods vs. 18.6 per 1000 km during non-seismic periods. The sighting rate for cetaceans was higher (30.9 detections/1000 km) during post-seismic periods, but the survey effort during post-seismic periods was low and the sightings involved very large aggregations of feeding gray whales.

Useable seal sighting rates were also higher during non-seismic than seismic periods, though the difference between seismic and non-seismic periods was not nearly as marked as for cetaceans. When all data are considered (meaning useable and non-useable), sighting rates for pinnipeds in water were actually highest during seismic periods. When considering only useable data, pinnipeds were seen in water more frequently during non-seismic periods. This was also true for pinnipeds on ice; however ice was less likely to be visible during seismic periods as it posed a navigational hazard. Detections of Pacific walruses in water were most frequent during post-seismic periods and nearly 0 during seismic periods. The extremely low number of detections could be an indication of displacement. If displacement was occurring, the high numbers of post-seismic sightings may indicate that animals were not displaced very far or for long periods of time.

The presence of fog (visibility <3.5 km) was the most common reason that sightings were considered non-useable. During seismic periods, the detection rate in non-useable periods was about ½ of that in useable periods, consistent with what would be expected during periods of poor vs. good visibility (Table 6.1). For non-seismic periods, the difference in detection rate between non-useable and useable periods was even greater than for seismic periods (Table 6.1).

Other Vessels.—While the *Gilavar* and *Kilabuk* were working in tandem, the vessels were typically within ~5 km of each other and often as close as a few hundreds of meters from each other. The location and proximity of the *Kilabuk* were extremely variable, and probably had some effect on the number of sightings and the behavior of marine mammals that were sighted. This effect, however, was not apparent to the MMOs in real time when they were observing marine mammals. Other than the *Kilabuk*, one other chase/supply vessel (the *Gulf Provider*) associated with the survey was sighted regularly. On some occasions this vessel relieved the *Kilabuk* and on other occasions the two vessels were present simultaneously. The seismic vessel *Western Patriot* was also operating in the area but was rarely close enough to be seen by the MMOs.

Distribution of Marine Mammals

Observations during the Chukchi Sea study indicate that phocid seals (spotted and ringed) were the most abundant marine mammals in the area (Tables 6.2, 6.3). It is expected that the majority of unidentified seals were ringed or spotted seals as bearded seals would be more easily confused with Pacific walruses (because of their size) and therefore classified as unknown pinnipeds. Pacific walruses were more abundant than bearded seals. All species of pinnipeds, with the exception of the one sighting of a ribbon seal, were seen during both seismic and non-seismic periods.

The gray whale was the most abundant species of cetacean, followed by the bowhead whale (Tables 6.2, 6.3). Harbor porpoises and minke whales were seen on multiple occasions and there was one sighting of a group of 3 fin whales plus one sighting of a single humpback whale. Harbor porpoises were seen during both seismic and non-seismic periods. The only large whale seen during seismic periods was one minke whale. The numerous gray whale sightings all occurred during non-seismic periods; however, it should be noted that the sightings of gray whales tended to be clustered and their distribution is more likely an indication of distribution of food resources than a response to seismic activity.

Specific locations of sightings are not mapped given the sensitivity of information about the exact locations where the seismic survey was done (see Chapter 2).

Marine Mammal Behavior

The data collected during visual observations provide information about behavioral responses of marine mammals to the seismic survey. The relevant data include estimated closest observed points of approach (CPA) to the vessel, movement relative to the vessel when the airguns were and were not firing, and observed behavior of animals at the time of the initial sightings.

Closest Observed Point of Approach

There was a statistically significant difference between the CPA distances for seals in water during seismic vs. non-seismic periods. When considering combined useable sightings from the *Gilavar* and *Kilabuk*, CPA during non-seismic periods was less than CPA during seismic periods (Wilcoxon rank sum test, $n = 56$ vs. 154; $Z = 6.139$, P 0.000; Table 6.4 and 6.5). When only *Gilavar* data are considered, the trend is reversed ($n = 56$ vs. 50; $Z = -2.3418$, P 0.0192). No meaningful comparison was possible for cetaceans because there was only one sighting from the *Gilavar* during seismic periods. Similarly, there were insufficient walrus data for statistical analyses of CPA. The mean CPA during seismic periods, as presented in Table 6.4, is underestimated if some animals avoided the airguns at distances beyond those where they could be detected by MMOs.

Although most sample sizes are small, the sighting-distance data from this study are not consistent with those from many previous seismic studies. In other studies, marine mammals were usually observed at greater distances from the vessel and lower sighting rates when the airguns were operating than when the airguns were silent (e.g., Smultea et al. 2004; Haley and Koski 2004; MacLean and Koski 2005; Holst et al. 2005a,b). This is also true for similar studies conducted in nearby Arctic regions (Harris et al. 2001; Haley and Ireland 2005).

Categories of Behavior

Marine mammal behavior is difficult to observe, especially from a seismic vessel, because individuals and/or groups are often at the surface only briefly, and there may be avoidance behavior. This causes difficulties in resighting those animals, and in determining whether two sightings some minutes apart are repeat sightings of the same individual(s). Only limited behavioral data were collected during this project because marine mammals were often seen at a distance from the vessel, and they were typically not tracked for long distances or durations while the vessel was underway. The two variables that were examined quantitatively to assess potential seismic effects on behavior were the categories of movement and behavior when the animal(s) were first observed (see Appendix Table E.1 for variables and definitions). The CPA distance recorded for each sighting was also an indicator of behavior (see above and Appendix Table G.3 for details on sightings). Results regarding movement and behavior are presented in Tables 6.6 and 6.7. (In those tables, cetacean data include only useable sightings from the *Gilavar*; however, seal and walrus data include useable sightings from both the *Gilavar* and the *Kilabuk*.)

TABLE 6.4. Closest observed points of approach (CPA) of useable marine mammal sightings from the Gilavar to the airguns during non-seismic and seismic periods during the Chukchi Sea survey 27 July–20 Sept. 2006.

Movement.—Movement was observed and recorded for 41 sightings of cetaceans (Table 6.6). (Of the total of 53 cetacean sightings, there were 12 sightings for which movement was either unknown or not recorded.) Of the 40 sightings during non-seismic periods for which movement was recorded, most were of cetaceans swimming parallel to the vessel (18 of 40, or 45%; Table 6.6) or swimming perpendicular (11 of 40, or 27.5%). The one cetacean sighting made during seismic activity was swimming away from the vessel.

TABLE 6.6. Numbers of useable sightings of marine mammals by movement category during seismic and non-seismic periods from the *Gilavar* (10 Jul.-23 Sept. 2006) and the *Kilabuk* (10 Jul.-4 Oct. 2006) within the Chukchi Sea. See Appendix E for definitions of movement categories.

[a] Includes only useable sightings as defined in *Acronyms and Abbreviations* .

[b] Cetacean sightings include only those from the *Gilavar* ; seal and Pacific walrus sightings include those from the *Gilavar* and the *Kilabuk* . All *Kilabuk* pinniped sightings were treated as non-seismic. See text for explanation.

Movement category was recorded for 119 seal sightings had movement records, of which 75 sightings were during non-seismic periods and 44 sightings were made during seismic periods. During both seismic and non-seismic periods, those seals in the water for which movement was recorded were most often seen swimming away from the vessel (40% during non-seismic; 41% during seismic; Table 6.6). Swimming perpendicular (25% during non-seismic; 18% during seismic) and swimming parallel (17% during non-seismic; 27% during seismic) were the next most frequently-observed movements in relation to the vessel. Only two sightings of seals in the water involved individuals swimming toward the vessel.

Of the 15 sightings of walruses in the water during non-seismic periods, six (40%) were of animals swimming away, five (33%) were of animals milling, and four (27%) were of animals swimming perpendicular. The one sighting of a walrus during seismic activity was swimming toward the vessel (Table 6.6).

The movement of pinnipeds first observed on ice was always categorized as hauled out and is therefore not presented in Table 6.6.

First Observed Behavior.—The most common "first observed behavior" of cetaceans, all but one sighting of which were during non-seismic periods, was blowing (43 of 52 sightings for which behavior was recorded, or 83%; Table 6.7). Looking and swimming/traveling were the most common "first observed behaviors" of seals in the water during non-seismic periods, accounting for 45% and 43% of the 159 non-seismic sightings respectively. However, swimming/traveling was observed first most often during seismic periods (41 of 59 sightings with behavior recorded, or 69%). Twenty-five per cent (15 of 59) of sightings of seals in the water during seismic periods were of animals looking. There were 17 sightings of Pacific walruses in the water during non-seismic periods, and one sighting during seismic periods. The first-observed behavior of 15 of those 18 sightings, including the one sighting during seismic, was swimming/traveling. The other three sightings were of animals looking at the vessel.

TABLE 6.7. Comparison of first observed behaviors of useable marine mammal sightings during non-seismic and seismic periods from the *Gilavar* (10 Jul.-23 Sept. 2006) and the *Kilabuk* (10 Jul.-4 Oct. 2006) within the Chukchi Sea. See Appendix E for definitions of behavior categories.

[a] Includes only useable sightings as defined in *Acronyms and Abbreviations*.

[b] Cetacean sightings include only those from the *Gilavar*; seal and Pacific Walrus sightings include those from the *Gilavar* and the *Kilabuk*. All *Kilabuk* pinniped sightings were treated as non-seismic. See text for explanation.

Mitigation Measures Implemented

A total of 10 power downs and 38 shut downs of the airguns were requested due to sightings of pinnipeds approaching or within the safety radii applied during the Chukchi Sea cruise (Table 6.8; for a full account of each power down and shut down, see Appendix H). The applied safety radii for pinnipeds were 600 m from the *Gilavar's* airgun array for a power down and 300 m from the array for a shut down (Table 5.1). These **safety radii** were larger than the estimated and measured 190 dB rms **sound level radii** for *Gilavar*'s 3- and 1-string airgun arrays (see Table 4.4), leading to the application of protective mitigation measures. The 190 dB rms sound level distance used in assessing the likelihood of exposures (Table 6.8) is also protective, since the single largest measured 190 dB rms distance was applied, when in fact the 190 dB rms distance is not uniform around the vessel (see Table 4.4). Sound levels are also not uniform with depth (Greene and Richardson 1988; Tolstoy et al. 2004a,b), so animals would need to dive well below the surface to encounter sound levels ≥190 dB rms near the measured sound level radii.

No power downs or shut downs were implemented, or needed, for cetaceans. During periods when the airguns were operating, there were two sightings of cetaceans within 1100 m of the *Gilavar*, i.e., within the applied "180 dB rms" safety radius of 1100 m for power downs (sightings 230 and 266, Appendix Table G.3). However, only the two mitigation guns (155 in^3) were firing during both of these sightings, so the airguns were essentially already "powered down". Neither cetacean entered the 180 dB rms sound level radius of 360 m around the two airguns and it is very unlikely that either of the animals was exposed to sound levels ≥180 dB rms.

Of the 48 interruptions of airgun operations for sightings of pinnipeds, 14 shut downs occurred when the *Gilavar* was using its mitigation airguns (155 in^3). A further nine shut downs (six during ramp-ups) and one power down (also during a ramp-up) occurred when the *Gilavar* was firing eight airguns (1049 in^3). However, the majority of mitigation measures were implemented when the full 24-airgun array (3147 in^3) was in use: 15 shut downs (two during ramp-ups) and nine power downs (four of which were during ramp-ups).

If an animal approaches the airgun array during a ramp-up sequence, it is difficult to evaluate the level of sound exposure the animal may have received before mitigation occurred. The number and combined volume of firing airguns is often not precisely known at specific times during ramp-up sequences. It was assumed that, within the first 15 min of a ramp-up sequence, the volume was 1049 in^3 (8 guns), after which time it was assumed to be the full 3147 in^3 (24 guns). The assumed volume of firing airguns during ramp-ups will in most cases be an overestimate, decreasing the likelihood that animals were exposed to sound levels ≥190 dB rms.

All power downs or shut downs were the result of individual pinnipeds, except for one sighting of two ringed seals (sighting 318, Table 6.8). The majority of the 48 power downs (10) and shut downs (38) were for unidentified seals (29), followed by spotted seals (9), ringed seals (8), bearded seal (1), and Pacific walrus (1).

Of the 10 power downs, nine occurred when the full 24−airgun 3147 in^3 array was firing, so the estimated 190 dB rms sound level distance was 460 m (Tables 4.4, 5.1). The one exception was a power down from the 1049 in^3 array, where the 190 dB rms distance was 420 m (Table 4.4). Two of the ten power downs were unnecessary, as the seals involved did not actually come within the 600 m safety radius. Of the eight seals within the 600 m safety radius, two did not enter the 190 dB rms sound level distance. The remaining six cases involved individuals that were "likely" or "very likely" exposed to a received sound level of ≥190 dB rms. Those six seals approached the airguns to distances ranging from 310 to 417 m and diving well below the surface before the power downs occurred. These six likely exposures to ≥190 dB rms include four unidentified seals, one ringed seal, and one spotted seal.

TABLE 6.8. List of power downs (PZ) and shut downs (SZ) of the airguns implemented for pinnipeds sighted in or near the *Gilavar*'s safety radii (600 m for power downs, 300 m for shut downs), during the Chukchi Sea seismic survey, 27 Jul.−9 Sept. 2006. No power downs or shut downs were implemented for cetaceans. See Appendix Table G.3 for more details on these sightings. Also see Appendix H for an account of each power down and shut down.

[b] Categories of likelihood of exposure range from least likely to most likely: Very unlikely, Unlikely, Likely, Very likely.

Considering the 38 full shut downs, for all cases but one, powering down to the mitigation airguns would have sufficed to avoid exposing animals to a sound level ≥190 dB rms. The one case where the full shut down was necessary, to avoid exposing an animal to ≥190 dB rms from the mitigation airguns (155 in^3), involved a single bearded seal (sighting 282, Appendix H). The seal was 327 m away from the *Gilavar* when the shut down was initiated, and subsequently approached the airguns within 5 m after the shut down, at which time it dove and was not seen again. The remaining 37 full shut downs occurred because the applied safety radii were more protective than the measured 190 dB rms sound level distances, as mentioned above.

Of the 38 shut-downs, there was one case that involved a single Pacific walrus (sighting 192, Table 6.8) where the individual did not enter the 600 m safety radius before the shut down occurred. Of the remaining 37 cases, there were only 18 sightings involving 18 seals where individuals actually entered the 190 dB rms sound level distance before the airguns were shut down. Fifteen of these seals were likely or very likely exposed to ≥190 dB rms, coming within 250 to 450 m of the airguns and diving well below the surface before the shut downs occurred. The remaining three seals (sightings 215, 264, and 282, Table 6.8) were each sighted within the 190 dB rms sound distance and remained at the surface until after the shut downs occurred. All three seals were likely exposed to ≥190 dB rms before they surfaced and were initially detected. The 18 seals likely exposed to ≥190 dB rms included 11 unidentified seals, five ringed seals, one spotted seal, and one bearded seal.

Overall, considering both power downs and shut downs, there were 24 cases when seals were exposed to ≥190 dB rms. These included 15 unidentified seals, six ringed seals, 2 spotted seals, and one bearded seal.

Estimated Number of Marine Mammals Present and Potentially Affected

It is difficult to obtain meaningful estimates of "take by harassment" for several reasons: ***(1)*** The relationship between numbers of marine mammals that are observed and the number actually present is uncertain. ***(2)*** The most appropriate criteria for "take by harassment" are uncertain and presumably variable among species and situations. ***(3)*** The distance to which a received sound level exceeds a specific criterion such as 190 dB, 180 dB, 170 dB, or 160 dB re 1 μPa (rms) is variable. It depends on water depth, source depth, water-mass and bottom conditions, and—for directional sources—aspect (Chapters 3 and 4; see also Greene 1997; Greene et. al. 1998; Burgess and Greene 1999; Caldwell and Dragoset 2000; Tolstoy et al. 2004a,b). ***(4)*** The sounds received by marine mammals vary depending on their depth in the water, and will be considerably reduced for animals at or near the surface (Greene and Richardson 1988; Tolstoy et al. 2004a,b) and further reduced for animals that are on the ice.

Disturbance and Safety Criteria

Table 5.1 shows estimated received sound levels at various distances from the *Gilavar*'s 3147 in^3 3-string airgun array. The 160 and 170-dB radii are assumed behavioral disturbance criteria. The 180 and 190 dB radii are safety radii, used in determining when mitigation measures were required. During this and many other recent projects, NMFS has required that mitigation measures be applied to avoid or minimize the exposure of cetaceans and pinnipeds to impulse sounds with received levels ≥180 dB and ≥190 dB re 1 μPa (rms), respectively. NMFS commonly assumes that cetaceans and seals exposed to pulsed sounds with received levels ≥160 dB rms might be disturbed, although there is little evidence that most pinnipeds or delphinids exposed to airgun sounds with levels just above 160 dB rms are disturbed. The safety and disturbance radii summarized in Table 5.1D were used after the field season to estimate numbers of marine mammals exposed to various received sound levels.

Two methods were applied to estimate the number of pinnipeds and cetaceans exposed to seismic sound levels strong enough that they might have caused disturbance or other effects. The procedures include ***(A)*** minimum estimates based on direct observations, and ***(B)*** estimates based on pinniped and cetacean densities obtained during this study. The actual number of individuals exposed to, and potentially affected by, strong seismic survey sounds likely was between the minimum and maximum estimates provided below.

Estimates from Direct Observations

The number of marine mammals observed close to the *Gilavar* during the Chukchi Sea survey provides a minimum estimate of the number potentially affected by seismic sounds. This is likely an underestimate of the actual number potentially affected. Some animals probably moved away before coming within visual range, and not all of those that remained would have been seen by observers.

Pinnipeds Potentially Exposed to Sounds ≥190 dB re 1 µPa (rms).—During this project, there were 48 sightings involving 49 pinnipeds that resulted in the implementation of mitigation measures (Table 6.8). Of these 48 cases, there were 47 cases involving 48 seals that were within the "190 dB rms" pinniped safety radius of 600 m around the *Gilavar*'s airguns. However, given that the safety radius was larger than the measured 190 dB rms sound level distance, only 24 seals from 24 sightings came within the 190 dB rms distance. Of these 24 seals, 21 seals were likely exposed to ≥190 dB rms, as they were seen diving within the 190 dB rms sound distance before mitigation was implemented. The remaining three seals did not dive before mitigation action was taken, but were still likely to have been ensonified at a level ≥190 dB rms before they surfaced and were initially detected. Based on direct observations in the field, the 24 animals that were likely exposed to ≥190 dB include 15 unidentified seals, six ringed seals, two spotted seals, and one bearded seal. One pinniped, a ribbon seal, was sighted within the 160 dB radius. However, this animal was hauled out on ice and would not have received sound levels high enough to be considered a "take" according to NMFS criteria.

Cetaceans Potentially Exposed to Sounds ≥180 dB re 1 µPa (rms).—There were two sightings involving two individual cetaceans, one harbor porpoise and one minke whale, within 1100 m around the *Gilavar*'s airguns when they were operating (sightings 230 and 266, Table G.3). However, there were only 2 airguns (155 in^3) operating during both sightings, so no power down was implemented. Neither cetacean came within the 180 dB rms sound level distance for the two operating airguns, so they were very unlikely to have been exposed to ≥180 dB rms. However, each of these cetaceans was observed within the 160 dB radius of the 2 guns (1.37km).

Estimates Extrapolated from Density

The numbers of marine mammals directly sighted during the Chukchi Sea study no doubt underestimated the actual numbers present because some animals present near the trackline would not be seen by the observers. During daylight, animals are missed if they are below the surface when the ship is nearby. Some other mammals, even if they surface near the vessel, are missed because of limited visibility, intervening ice, glare, or other factors limiting sightability. High sea state (Bf) was a significant factor during limited periods of this cruise. Also, sound levels were estimated to be ≥160 dB re 1 µPa (rms) out to 8 km. This distance is well beyond those at which MMOs can detect even the more conspicuous animals under favorable sighting conditions during daytime. Furthermore, marine mammals could not be seen effectively during periods of darkness, which occurred for increasing numbers of hours per day after 14 August and nighttime observations were generally not required or attempted except prior to and during nighttime ramp-ups.

Also, some animals may have avoided the area near the seismic vessel while the airguns were firing (see Richardson et al. 1995, 1999; Stone 2003; Gordon et al. 2004; Smultea et al. 2004). Within the assumed 160–170 dB radii around the source (i.e., ~4.7–8 km), and perhaps farther away in the case of the more sensitive species and individuals, the distribution and behavior of pinnipeds and cetaceans may have been altered as a result of the seismic survey. This could occur as a result of reactions to the airguns, or as a result of reactions to the *Gilavar* or the *Kilabuk* themselves. The extent to which the distribution and behavior of pinnipeds might be affected by the airguns is uncertain, given variable previous results (Thompson et al. 1998; Harris et al. 2001; Moulton and Lawson 2002; Miller et al. 2005).

However, it is safe to assume that some pinnipeds that were on the ice as the two ships approached would have gone into the water in response to the *Kilabuk* before they were in view of observers on the *Gilavar*. Likewise, it is safe to assume that some cetaceans when approached by the seismic survey would have moved away before they were in view.

The methodology used to estimate the areas exposed to received levels ≥160 dB, ≥170 dB, ≥180 dB and ≥190 dB was described briefly in Chapter 5 *Monitoring and Mitigation Methods* and in more detail in Appendix E. Densities were based on data collected from the three vessels (*Gilavar*, *Kilabuk*, and *Gulf Provider*) during SOI's seismic operations in the Chukchi Sea. The density data are summarized in Appendix Table I.1..

The aforementioned densities were used to estimate both the number of *individual* marine mammals exposed to 160, 170, 180, and 190 dB, and the number of *exposures* of different individual marine mammals. These numbers provide estimates of the number of animals potentially affected by seismic operations, as described in Chapter 5 and Appendix E.

The estimates provided here are based on the actual amount of seismic surveying during this project. In contrast, the estimates provided in the IHA applications for this project (SOI 2005a,b) were based on the then-anticipated amount of survey, with an allowance for the possibility that some lines would be surveyed more than once. The estimates in the IHA applications assumed that there would be more seismic surveying than actually occurred. Thus, the present estimates are lower than those in the IHA application even though they are based on comparable density data. In addition, the following estimates assume that all mammals present were well below the surface where they would be exposed to the sound levels predicted in Table 5.1 at a given distance. In fact, some pinnipeds were hauled out on the ice, and remained there as the ship passed, and some pinnipeds and cetaceans in the water might remain close to the surface, where sound levels would be reduced by pressure-release effects (Greene and Richardson 1988). Finally, some pinnipeds and cetaceans may have moved away from the path of the *Gilavar* before it arrived, either because the *Kilabuk* frequently traveled in front of *Gilavar*, or because of an avoidance response to the approaching *Gilavar* and its airguns. Thus, the following estimates, though lower than those in the IHA Application, are nonetheless likely to overstate actual numbers exposed to various received sound levels.

Estimates of the densities of pinnipeds and cetaceans are given in Table I.1, including approximate corrections for sightability biases. These corrected densities were used to estimate the number of marine mammals that were exposed to various received levels of airgun sound, and thus potentially affected by seismic operations (Tables 6.9, 6.10).

Pinnipeds.—Table 6.9 summarizes the estimated numbers of pinnipeds that might have been exposed to received sounds with various levels relative to the number of "takes" requested in SOI's IHA application for the Chukchi Sea. These estimates are based on the ensonified area figures from Table E.1 and the density data from Table I.1. The latter Appendix table gives the density estimates derived from vessel-based surveys during both non-seismic and seismic periods. Note that the estimated numbers in Table 6.9A, based on density data from non-seismic periods, represent the pinnipeds that would have been exposed had the animals not shown localized avoidance of the airguns or the ship itself, and assume that all pinnipeds present were in the water. Some of the animals calculated (based on density) to be within the ≥190-dB zone would in fact move away before being exposed to sounds that strong. Also, some of those calculated to be in the ≥160- or ≥170 dB zones would be on the ice and not exposed to the underwater sounds.

TABLE 6.9. Estimated numbers of exposures, and estimated numbers of individual pinnipeds within the Chukchi Sea that might have been exposed to received levels of sounds at levels shown, divided into (1) seals and (2) Pacific walrus. Requested takes for the Chukchi Sea are also shown. Estimates are based on "corrected" densities of pinnipeds calculated from sighting effort (see text in Chapter 6 for species-specific estimates).

Exposure level in dB re 1µPa (rms)	A. Based on Non-seismic density[a]		B. Based on Seismic density[a]		*Requested Take*
	Exposures	Individuals	Exposures	Individuals

190	134	49	5	2	

[a] These density estimates are presented in Appendix Table I.1

TABLE 6.10. Estimated numbers of exposures, and estimated numbers of individual cetaceans within the Chukchi Sea that might have been exposed to received levels of sounds at levels shown. Requested takes for the Chukchi Sea are also shown. Estimates are based on "corrected" densities of cetaceans calculated from sighting effort (see text in Chapter 6 for species-specific estimates).

Exposure level in dB re 1µPa (rms)	A. Based on Non-seismic density[a]		B. Based on Seismic density[a]		*Requested Take*
	Exposures	Individuals	Exposures	Individuals	
160	3089	198	62	4	422
170	1715	131	34	3	
180	532	91	11	2	
190	172	63	3	1	

[a] These density estimates are presented in Appendix Table I.1

(A) ≥160 dB (rms): We estimate that there would have been ~20,512 exposures of ~1317 different individual seals to airgun pulses with received levels ≥160 dB re 1 µPa (rms) during the survey if all seals were in the water and showed no avoidance of the ≥160 dB zone (Table 6.8A). Based on the available densities and prorating of unknown individuals, 4558 of the exposures would have been of spotted seals, 2012 of bearded seals, 1550 of ringed seals, and 257 of ribbon seals. The sighting rate of spotted seals was higher than

expected given the known prevalence of ringed seals in the area. Pacific walruses are estimated to have been exposed to ≥160 dB on 2397 occasions. Prorating of unidentified individuals may have artificially inflated the estimated takes of two species and underestimated the takes of one species. It is likely that ringed seals, known to be very common in the area, actually comprised a higher proportion of unidentified animals than did spotted seals. In addition, only one ribbon seal was sighted throughout the entire cruise and it is not likely that any significant number of this species were present during seismic operations.

The numbers of different individual seals and walruses that might have been exposed to levels ≥160 dB rms, calculated from sighting rates during non-seismic periods, were only 1317 and 154 as compared with the corresponding estimates of numbers of exposures (20,512 seals and 2397 walruses). The lower numbers of individuals than of exposures is a result of the fact that many areas were ensonified repeatedly to ≥160 dB as the seismic vessel moved back and forth along different seismic lines. Most animals that lingered in the area would have been exposed to levels ≥160 dB numerous times over an extended period, but the number of different individuals so exposed would be far less than the estimated number of exposure incidents.

(*B) ≥170 dB (rms):* On average, pinnipeds may be disturbed only if exposed to received levels of airgun sounds ≥170 dB re 1 µPa (rms). If so, then the estimated number of exposures would be ~56% of the corresponding estimates for ≥160 dB, based on the proportionally smaller areas exposed to ≥170 dB (Table E.1). Overall, there would have been ~11,389 exposures of seals, involving ~872 individuals, and 1331 exposures of walruses, involving 102 individuals, to seismic sounds ≥170 dB (Table 6.9A). Again, numbers of different individuals exposed were far lower than numbers of exposures (Table 6.9A).

(C) ≥180 dB (rms): Some pinnipeds no doubt were within the 180 dB radius (estimated as being up to 1.4 km, Table 4.4) around the operating airguns but were missed by the observers even during airgun operations conducted in good visibility conditions. It is estimated that there were 3531 exposures of 607 individual seals and 413 exposures of 71 individual walruses to sounds ≥180 dB (Table 6.9A). These figures assume that there was no effective avoidance by pinnipeds of the 180 dB radius around the approaching airguns.

(*D) ≥190 dB (rms):* Based on densities calculated from sighting rates during non-seismic periods, we estimated that there would have been 1145 exposures of 416 different seals and 134 exposures of 49 different walruses to airgun sounds at ≥190 dB (rms) if there were no avoidance (Table 6.9A). Even the smaller of these estimates is far higher than the number of pinnipeds (n = 21) that direct observations indicated were possibly exposed to ≥190 dB (Table 6.8). Some pinnipeds within the 190 dB radius presumably were missed during times when MMOs were on watch as well as at night when MMOs generally were not on watch. Even during times when MMOs are on watch, some seals at the surface can be missed due to brief surface times, poor visibility, rough seas, and other factors. Because of this, density-based estimates of exposures and exposed individuals are higher than those based on direct observation. However, estimates based on densities during non-seismic periods may be overestimates. The *Kilabuk* might be expected to displace some pinnipeds from the trackline before the *Gilavar* arrived, and some additional pinnipeds likely swam away in response to the approaching *Gilavar* to avoid exposure to such strong seismic sound. Therefore, the actual number exposed to ≥190 dB rms was probably lower than the above estimates. However, there was no tendency for observed CPA distances to be higher in seismic than non-seismic periods (Table 6.4). Thus, it is likely that actual numbers exposed to ≥190 dB rms were closer to those estimated based on density data than to the much lower figures based on direct observation.

Estimates Based on Densities during Seismic Periods: The estimates quoted in the above paragraphs are all based on densities recorded during non-seismic periods. Densities of seals recorded during seismic periods were similar to those recorded during non-seismic, but densities of unidentified pinnipeds and of walruses recorded with seismic were markedly lower than those during non-seismic periods (Table I.1). Lower densities might be expected during seismic periods, either because of displacement (to the extent it occurs) or the tendency of seismic activity to take place further away from pack ice. (Arctic pinnipeds tend to concentrate near ice in summer.) On the other hand, locally abundant food resources near seismic track lines may be responsible for occasional high densities there. On several occasions the *Gilavar* passed through very strong tide rips and fronts. These areas frequently contain prey biomass higher than surrounding areas and thus attract seals (Suryan and Harvey 1998). The minimum numbers of exposures and minimum numbers of individuals exposed, based on the corrected densities recorded during seismic periods, are summarized in Table 6.9B.

Overall, these minimum figures are somewhat lower than those based on densities during non-seismic periods. Again, the minimum estimates of the numbers of individuals exposed are much lower than the minimum estimates of numbers of exposures to various received levels. In other words, many of the individuals pinnipeds exposed to a given sound level were exposed to that level several times. This reflects the degree of overlap in the ensonified areas around different seismic lines.

Cetaceans.—The estimated numbers of cetaceans that might have been exposed to various levels of received sounds, relative to the number of "takes" requested in the IHA application, are summarized in Table 6.10. The density data used to calculate these numbers, for non-seismic as well as seismic periods, are presented in Table I.1. Note that the estimated numbers in Table 6.10A represent the cetaceans that would have been exposed had the animals not shown localized avoidance of the airguns or the ship itself. Many of the animals calculated (based on density) to be within the ≥180- or ≥190-dB zones would in fact move away before being exposed to sounds that strong. This is presumably at least part of the reason for the fact that estimates based on sightings during seismic periods (Table 6.10B) were much lower than those during non-seismic periods (Table 6.10A).

(A) ≥160 dB (rms): We estimate that there would have been ~3089 exposures of ~198 different individual cetaceans to airgun pulses with received levels ≥160 dB re 1 µPa (rms) during the survey if all cetaceans showed no avoidance (Table 6.10A). Based on the available densities, 1824 of the exposures would have involved gray whales, 589 bowhead whales, 179 beluga whales, 388 harbor porpoises, 54 fin whales, 40 minke whales, and 19 killer whales. As with pinnipeds, the prorating of unidentified individuals may have resulted in a slight overestimation of takes of less frequently seen species. Minimum estimates of the numbers of different individuals exposed to ≥160 dB were far lower than were the estimates of the number of exposures to that level. This reflects the overlap in the ensonified areas around different seismic lines, and the fact that an animal remaining in the area would have been exposed repeatedly to ≥160 dB.

(B) ≥170 dB (rms): On average, some odontocete species may be disturbed only if exposed to received levels of airgun sounds ≥170 dB re 1 µPa (rms). If so, then the estimated number of exposures would be ~56% of the corresponding estimates for ≥160 dB, based on the proportionally smaller areas exposed to ≥170 dB. Overall, there would have been ~1715 exposures of cetaceans, involving ~131 individuals, to seismic sounds ≥170 dB (Table 6.10A).

(C) ≥180 dB (rms): If there were no avoidance of airgun noise by cetaceans, it is estimated that there would have been ~531 exposures of ~91 individual cetaceans to seismic sounds ≥180 dB (Table 6.10A). However, most of these cetaceans probably moved away before the airguns were close enough to create a

received level ≥180 dB. As noted earlier, there were only two cetacean sightings from *Gilavar* when airguns were operating. It is possible that some additional cetaceans were present within the 180dB radius and not seen by the MMOs during good visibility conditions. However, under those conditions, most cetaceans present probably were seen.

Estimates Based on Densities during Seismic Periods: Only one species, the harbor porpoise, had useable sightings sufficient for the calculation of a density applicable to periods of seismic activity (Table I.1). The density of harbor porpoises during non-seismic periods was significantly higher. This may represent avoidance of the seismic operation by harbor porpoises. It could also be related, in part, to the fact that seismic surveys did not occur in close proximity to ice, where food was likely abundant. Based on the corrected densities recorded during seismic periods, the minimum numbers of exposures and minimum numbers of individuals exposed are summarized in Table 6.10B.

BEAUFORT SEA MONITORING

Vessel-based Monitoring Effort and Marine Mammal Encounter Results

This section summarizes the visual monitoring effort and marine mammal sightings from the *Henry Christoffersen* during the Beaufort Sea shallow hazards, bathymetric, and seismic survey work, 3 August to 3 October 2006. Summaries of results from visual monitoring are presented here, with more detailed data presented in Appendix G, including monitoring effort in both kilometers and hours (Tables G.4, G.5). A general summary of effort and sightings is shown in Table ES.1. All marine mammals were observed inside the study area shown in Figure 6.1, as no monitoring occurred during transit to and from Kaktovik through the Canadian Beaufort Sea before 3 August or after 3 October 2006 (Table G.7).

Visual Survey Effort

MMOs observed primarily from the conning tower of the *Henry C.* (eye-height ~15.4 m above water; 96.2% of watch time), with the remaining observations conducted from the bridge (eye-height ~8.4 m). During 8213 km of *Henry C.* cruise operations within the study area in the Alaskan Beaufort Sea, there was 5145 km of visual observation effort over 526 h; of that, 3239 km of effort over 296 h was classified as "useable" (Tables ES.1, G.4). Useable survey effort, subdivided by whether the airguns were firing or not and water depth strata, is shown in Appendix G (Table G.4). Seismic survey effort with the *Henry C.*'s small airgun system was very limited because of persistent, heavy, ice conditions. Airguns were operated for only 98 km over 10 h, with 4 h of airgun operations classified as useable for analysis purposes.

Beaufort Wind Force (Bf sea state) during observations ranged from 0 to 5 within the study area, with 41.6% of the total effort and 45.9% of the useable effort (in h) occurring during conditions of Beaufort 1 (Table G.5). Most useable observations were conducted during conditions with Bf ≤ 2 (73.9% in h; Table G.5). The prevailing low sea state was typically due to heavy floe ice coverage and the proximity of the vessel to pack ice throughout the survey area. None of the observations within the study area were deemed "non-useable" because of high Beaufort Wind Force.

Visual Sightings of Marine Mammals and Other Vessels

Numbers of Marine Mammals Seen.—An estimated 451 individual marine mammals were seen in 412 groups through the study area (Table 6.11). This included, during systematic observation periods, 408 sightings of seals (managed by NMFS) plus 4 sightings of polar bears (managed by USFWS). No walruses were identified from the *Henry C.* A detailed list of sightings is provided in Appendix G (Table G.6).

FIGURE 6.1. Beaufort Sea study area where the *Henry C.* conducted shallow hazards, bathymetric, and seismic surveys, 3 Aug. to 3 Oct. 2006. Monitoring effort began and ended in Kaktovik, Alaska.

Three different seal species were identified, with ringed seals being the most frequently identified species (n = 90 individuals in 80 groups), followed by spotted seals (n = 75 in 65 groups; Table 6.11). In addition, 15 groups (16 individuals) of bearded seals were observed. Of the 181 seals in the study area that were identified by MMOs, 90 (or 49.7%) were ringed seals. Most of the unidentified seals (n = 261 individuals in 248 groups) were likely ringed seals given the visual monitoring results and the known occurrence of this species throughout the study area. However, the unidentified seals moved too rapidly or were too far away for the observer to make a positive identification. Also, it seems likely that some of the seals identified as spotted seals were in fact ringed seals, given the much higher frequency of ringed than spotted seal sightings in the study area in the past.

No animal deaths were observed during monitoring, but on 12 August 2006 a polar bear was observed on ice feeding on a dead seal. The seal's death was likely due to direct predation, and was not attributed to seismic activity, as no seismic gear had been deployed from the *Henry C.* in over three days.

The majority of the 412 sightings (66.5% or 274 groups) within the study area were "useable" (Table 6.11). These "useable" sightings, along with corresponding effort data, are the basis for the ensuing analyses comparing sighting rates and behaviors of marine mammals seen during the cruise.

[a] Useable sightings are those made during useable daylight periods of visual observation, as defined in *List of Acronyms and Abbreviations*.

[b] Sightings of pinnipeds on ice and polar bears that occurred during "useable" sighting conditions.

Sightings with Airguns On.—No marine mammal sightings were noted during the 10 h (4 h useable) while the airguns were operating. There were three seal sightings during 7 h of post-seismic observation effort, all of which were classified as non-useable (Tables ES.1, 6.11). Thus, all useable sightings were

recorded during non-seismic periods, which constituted the overwhelming majority of the observation time (Tables ES.1, 6.11). No power downs or shut downs were required during seismic activity, as no marine mammals were sighted in the water within the 190 dB safety radius around the operating airguns, and no whales were sighted from the *Henry C.*

Sighting Rates.—The lack of sightings while the airguns were on (0 sightings in 10 h, of which 4 h were useable) could simply reflect the brief duration and location of seismic operations. However, it was also consistent with the possibility of a reduced sighting rate with seismic operations as compared to that in non-seismic periods (409 groups in 510 h, or 274 groups in 292 useable hours—Tables 6.11, G.4).

Sighting rates (# groups sighted per unit effort) during various types of MMO effort are presented in Table 6.12. During post-seismic operations, the sighting rate (in groups per km, all effort considered) was about half that during non-seismic conditions (35.3 vs. 82.4 groups/1000 km; Table 6.12).

The lower sighting rates under seismic and post-seismic conditions than under non-seismic conditions could have resulted if there was avoidance of airguns, but could also have occurred because the seismic operators took advantage of minimal ice conditions to conduct seismic activities. Operating the seismic gear away from pack ice margins and floe ice reduces the danger of damaging equipment in the ice. In summer and early fall, seals in the Beaufort Sea typically favor areas near drifting ice (Moulton and Lawson 2002). Polar bears would also presumably favor these same areas because of the higher density of seals. Fewer marine mammal encounters were expected in the open water where the seismic activities were conducted than within the ice floes and along the ice margin where much of the non-seismic observation effort was conducted. In non-seismic periods, the highest sighting rates were for pinnipeds in water (85.2 seals/1000 km of useable effort), distantly followed by polar bears (0.9 bears/1000 km) and pinnipeds on ice (0.3 seals/1000 km). The large difference in sighting rates between seals in water and seals on ice could be due in part to seals that were initially hauled out on ice entering the water as the vessel approached. Useable sightings only occurred during non-seismic periods.

Reduced visibility due to fog (visibility <3.5 km) was the most common reason that sightings and effort were considered non-useable (53.9% of non-useable data), followed by insufficient ship speed (speed < 2 knots, 32.6% of non-useable data). During non-seismic periods, the detection rate of non-useable sightings was about ⅞ of that for useable sightings (Table 6.12), which is a rather high fraction. In other studies, including the 2006 *Gilavar* effort in the Chukchi Sea (Table 6.1), sighting rates during non-useable periods have often been proportionally lower relative to those during useable periods.

Other Vessels.—The IHA required that MMOs record the number and characteristics of vessels <5 km from any marine mammal sightings (Appendix A). There were few vessels near the *Henry C.* during the 2006 monitoring period. Vessels that were present in the eastern half of the study area were generally barges. Most of these vessels were at distances >5 km; however two vessels were sighted at ~3.5 km from the *Henry C.* No marine mammals were sighted while another vessel was known to be within 5 km of the *Henry C.*; therefore, no obvious reactions by marine mammals to other vessels were observed.

Distribution of Marine Mammals

Marine mammal sightings in the study area are listed in Table G.6. Observations during the Beaufort Sea operations indicate that, as expected, the ringed seal was the most abundant species in the study area (Table 6.11). The large number of ringed seal sightings was expected based on limited previous survey efforts. Ringed seals were seen throughout the survey area wherever visual observations occurred, including before and after seismic operations (Fig. 6.1; Tables 6.11, G.6). The majority of mammal sightings occurred in the southern portion of the cruise, where ice coverage was presumably.

[b] Includes the "Post-seismic" category.

greater, and could be considered the ice margin. The lowest concentration of marine mammal sightings occurred along the more northerly parts of the tracklines where ice coverage was less dense, or occurred outside the shallow-hazards survey areas, where there was less observation effort.

Polar bears were sighted infrequently, but throughout the duration of the cruise, in areas close to land and ice. Useable sightings occurred during August and September 2006, and there was a non-useable sighting in October. Of the two sightings in August, both were on ice. The first sighting was of a single adult bear feeding on a seal. The bear did not react overtly to the presence of the vessel. The second sighting was of a mother and cub. Both bears entered the water upon noticing the vessel and began swimming away. The single observation in September consisted of a lone adult swimming parallel to and heading astern of the vessel. The behavior of the animal did not appear to be altered due to vessel presence. On 1 October 2006, there was a sighting of 2 adults and 3 cubs resting on Cross Island; this was classified as "non-useable" due to insufficient visibility. An additional opportunistic sighting was recorded at Cross Island on 30 September 2006, but the data were not included in the results because the vessel was anchored when the observation occurred. Two adults and four other bears were resting on ice near whale bone piles north of the island.

Marine Mammal Behavior

The data collected during visual observations provide information about behavioral responses of marine mammals to the seismic survey. The relevant data collected from the *Henry C.* include estimated closest observed points of approach (CPA) to the vessel, movement relative to the vessel when the airguns were not firing, and observed behavior of animals at the time of the initial sightings. CPA of marine mammals to the vessel was calculated from the location airguns would have been positioned if deployed.

Closest Observed Point of Approach

The mean CPA for pinnipeds (seals) in water was 249 m (n = 271), which was about 1/6th of that for polar bears on ice and in the water combined (1486 m; n = 3). These figures consider only useable sightings, all of which were during non-seismic periods (Table 6.13). The difference is reduced if only the animals in water are considered (249 m vs. 593 m; n = 271 vs. 2), as the most distant polar bear sighting was on land. In the absence of any sightings during seismic periods, nothing can be said about CPA values during seismic vs. non-seismic periods.

TABLE 6.13. Closest observed points of approach (CPA) of useable marine mammal sightings during the *Henry C.'s* non-seismic and seismic operating periods in the Beaufort Sea, 3 August to 3 October 2006. No sightings were observed during seismic activity. All pinnipeds were seals.

		Non-seismic			
Taxonomic Group[a]	**No. of Sightings**	**Mean CPA (m)**	**s.d.**	***n***	**Range (m)**
Pinnipeds in Water	271	249	200	271	1301
Pinnipeds on Ice	1	97	--	1	--
Polar Bears	3	1486	1555	3	2943

[a] Includes only useable sightings as defined in *Acronyms and Abbreviations.*

For seals in water, the mean CPA distance found during this project was 249 m (n = 271). The mean CPA distance would be less than the mean of the initial sighting distances. Nonetheless, the mean CPA value for 2006 is higher than the mean initial sighting distances in 5 of 6 prior years of seismic monitoring in the Alaskan Beaufort Sea: In 1996 to 2001, mean sighting distances to seals observed during non-seismic periods ranged from 113 m in 1998 to 294 m in 2000 (Table 3.9 *in* Moulton and Lawson 2002). The relatively high mean value in 2006 (despite the fact that it summarizes CPA distances and not initial sighting distances) is probably related to two factors: the good visibility afforded by the high conning tower on the *Henry C.*, and to the relatively low Beaufort state that prevailed due to the proximity of ice.

Categories of Behavior

The two behavior variables that were examined quantitatively were the same as for the Chukchi Sea (see earlier): behavior category and movement category when the animal(s) were first observed (see Appendix E for variables and definitions). The CPA distance recorded for each sighting was also an indicator of behavior (see above and Appendix E).

Sample sizes for this cruise were small and there were no useable sightings during the limited seismic operations. However, previous studies in the Alaskan Beaufort Sea have provided comparable data on seal behavior in the presence and absence of airgun operations (e.g., Moulton and Lawson 2002). The 2006 data from non-seismic periods could be useful as a basis of comparison with any future related results. The 2006 results are presented in Tables 6.14 and 6.15.

Movement.—During non-seismic periods, pinnipeds (mainly ringed seals) in the water were most often seen swimming toward the vessel (24.6% of sightings for which "movement category" was recorded; Table 6.14). The second most frequently observed movement was swimming parallel to the vessel (12.5%). A single record of a pinniped first observed on ice was categorized as hauled out (although it dove into the water from the hauled out position).

A polar bear first observed on ice was included with all other polar bear sightings in Table 6.14 and recorded as stationary (no movement).

First Observed Behavior.—Across all categories of animals, the most common "first observed behavior" during non-seismic periods was "looking" (Table 6.15). Looking was the first observed behavior for 30.5% of the seal sightings during non-seismic periods. However, pinnipeds observed in the water were nearly as likely (24.4%) to dive as they were to look at the vessel as it approached (Table 6.15). The single pinniped that was observed hauled out on ice dove into the water as the vessel passed (Table 6.15). Polar bear activity was variable, as they were observed actively feeding or swimming during three separate useable sightings.

Mitigation Measures Implemented

No power downs or shut-downs of the airguns were necessary or requested due to marine mammal sightings within the 180 and 190 dB safety radii during the Beaufort Sea shallow-hazards survey. All sightings of marine mammals occurred during non-seismic periods.

Estimated Number of Pinnipeds Present and Potentially Affected

It is difficult to obtain meaningful estimates of "take by harassment" for several reasons, as enumerated in the corresponding Chukchi Sea section, earlier. During the 2006 vessel-based monitoring in the Beaufort Sea, there were additional factors to consider: • Several of the sightings were of seals and polar

TABLE 6.14. Movement categories recorded for useable marine mammal sightings in water during the *Henry C.*'s Beaufort Sea cruise, 3 Aug. to 3 Oct. 2006. All useable sightings were non-seismic and are presented as number of groups with number of individuals in parentheses. See Appendix E for definitions of movement categories. All pinnipeds were seals.

with seismic operations was very limited, and there were no useable marine mammal sightings with seismic operations.

Disturbance and Safety Criteria

Table 5.2 shows estimated received sound levels at various distances from a 4-airgun array with total volume 240 or 280 in^3. The 120, 160, and 170 dB rms radii quoted in Table 5.2B,C are assumed disturbance criteria, and they are based on limited acoustic measurements in the Beaufort Sea made by Greeneridge Sciences (see Chapter 4). The most protective empirical measurements by Greeneridge Sciences (see Chapter 4, Table 5.2B) were used to calculate areas ensonified and potential exposures.

The 180 and 190 dB radii are safety radii, used in determining when mitigation measures were required. During this and many other recent projects, NMFS has required that mitigation measures be applied to avoid, or minimize, the exposure of cetaceans and pinnipeds to impulse sounds with received levels ≥180 dB and ≥190 dB re 1 µPa (rms), respectively. Given the lack of mammal sightings during SOI's brief periods of airgun operations in the Beaufort Sea in 2006, no power downs or shut downs of the airguns were required. However, the safety and disturbance radii were used after the field season to estimate numbers of marine mammals exposed to various received sound levels.

This section applies two methods to estimate the number of pinnipeds exposed to seismic sound levels strong enough that they might have caused disturbance or other effects. The first procedure is based on direct observations of seals exposed to airgun sounds. The second is based on an indirect estimation process that involves calculating the total areas ensonified by various levels of sound (Appendix E, Table E.3), and multiplying those areas by the estimated density of seals within the study area (Appendix I, Table I.2).

Estimates from Direct Observations

The number of marine mammals observed close to the *Henry C.* during Beaufort Sea monitoring provides a minimum estimate of the number potentially affected by seismic sounds. This is likely an underestimate of the actual number potentially affected. Some animals probably moved away before coming within visual range, and not all of those that remained would have been seen by observers.

Seals Potentially Exposed to Sounds ≥190 dB re 1 µPa (rms).—During this project, no marine mammals were sighted within the small safety radius around the airguns while seismic operations were conducted. The estimated 180 dB and 190 dB radii shown in Table 5.2 are the *maximum* distances from the airguns where sound levels were expected to be ≥180 or ≥190 dB re 1 µPa (rms). These distances would have been applied as mitigation radii if any marine mammals had been seen during airgun operations. As no marine mammals were seen during airgun operations in the Beaufort Sea, the direct estimate of numbers exposed to ≥190 dB rms was zero.

Marine Mammals Potentially Exposed to Sounds ≥160 dB re 1 µPa (rms).—Likewise, no marine mammals were sighted in the water under "useable" (or non-useable) conditions during the Beaufort Sea cruise when the airguns were operating (Tables ES.1, G.6).

Estimates Extrapolated from Density

The numbers of mammals directly sighted by MMOs underestimate the actual numbers, as described in the Chukchi Sea section earlier. Indirect estimates based on the ensonified area and estimated mammal density provide alternative estimates that can avoid this underestimation.

The methodology used for the indirect estimates was described briefly in Chapter 5 and in further depth in Appendix E. Methods used to estimate the areas exposed to received levels ≥160, ≥170, ≥180 and ≥190 dB were described there. Densities of marine mammals in the study area were estimated based on direct observations during non-seismic periods, analyzed using standard line-transect estimation procedures, and adjusted to allow for missed animals.

The aforementioned densities were used to estimate both the number of different *individual* marine mammals exposed to 160, 170, 180, and 190 dB rms, and the number of *exposures* of marine mammals to the various levels. As discussed in the Chukchi Sea section, estimated number of exposures will exceed the estimated number of different individuals exposed if the airguns are towed back and forth through the same region a number of times, exposing some animals to airgun sound on more than one pass.

The estimates provided here are based on the actual airgun operations during the Beaufort Sea portion of this project. In contrast, the estimates provided in the IHA application and EA for this project were based on the then-anticipated amount of survey. The estimates in the IHA Application assumed that SOI would conduct far more seismic surveying in the Beaufort Sea than actually occurred. The requested "takes" by Shell Offshore Incorporated in the Beaufort Sea included those from the planned 3-D work that was not conducted. Thus, the present estimates of numbers actually exposed to various sound levels are lower than those anticipated in the IHA Application. In addition, the following estimates assume that all mammals present were well below the surface, and that mammals did not move away from the path of the approaching *Henry C.* Those assumptions probably did not apply to all animals, so (as described earlier for the Chukchi Sea), indirect estimates based on densities in non-seismic periods are probably overestimates. Also, the estimated number of animals exposed could be further overstated because the size of the airgun array assumed in these calculations (4 airguns totaling 280 in^3) exceeded the size used for the majority of seismic acquisition in the Beaufort Sea (2 guns totaling 140 in^3).

Pinnipeds.—Estimates of the densities of pinnipeds in the Beaufort Sea study area are given in Appendix I (Table I.2), based on useable sightings and observation effort from the *Henry C.* during non-seismic periods, and including approximate corrections for sightability biases. These corrected densities were used to estimate the number of marine mammals that were exposed to various received levels of airgun sound, and thus potentially affected by seismic operations (Table 6.16). The table summarizes the estimated numbers of seals that might have been exposed to sounds with various received levels, along with the number of "takes" for which authorization was requested in Shell's IHA Application for the Beaufort Sea (SOI 2005a). As noted in the preceding paragraph, the numbers in Table 6.16 are probably overestimated.

NMFS commonly specifies that marine mammals exposed to pulsed sounds with received levels ≥160 dB re 1 µPa (rms) should be considered potentially disturbed. However, most pinnipeds are unlikely to be disturbed appreciably by airgun sounds when exposed to received levels of 170 dB (Harris et al. 2001; Moulton and Lawson 2002). These are not considered to be "all-or-nothing" criteria; some individual mammals may react strongly at lower received levels, but others are unlikely to react strongly unless levels are substantially above 160 or 170 dB.

(A) ≥160 dB (rms): We estimate that there would have been ~180 exposures of ~149 different individual seals (ringed, bearded, and spotted) to airgun pulses with received levels ≥160 dB re 1 µPa (rms) during the shallow-hazards survey if all seals were below the surface of the water and showed no avoidance of the approaching vessel, and if the 4-airgun 280-in^3 source had been used for all airgun operations (Table 6.16). Given the predominance of ringed seals in the Beaufort Sea, most of the exposures would have been of ringed seals, with lesser numbers of exposures of bearded and spotted seals.

TABLE 6.16. Estimated numbers of exposures, and estimated minimum numbers of individual pinnipeds (ringed seals, spotted seals, and bearded seals) that might have been exposed, to sounds with various received levels during airgun operations from the *Henry C*. Numbers of exposures are overestimated as the calculations assume that all seals were in the water well below the surface, that they did not move away from the approaching airguns, and that all airgun operations were with a 4-airgun 280 in^3 array (see text). Also shown in boldface is the "harassment take" authorized by NMFS under the IHA.

Exposure level in dB re 1 µPa (rms)	**Estimated total**		***Requested Take***
	Exposures	**Individuals**	
160	180	149	***2206***
170	66	63	
180	24	23	
190	9	8	

(B) ≥170 dB (rms): Seals were unlikely to be disturbed unless exposed to received levels of airgun sounds ≥170 dB re 1 µPa (rms). If so, then the estimated number of exposures would be ~37% of the corresponding estimates for ≥160 dB, based on the proportionally smaller areas exposed to ≥170 dB. Overall, there would have been ~66 exposures of seals, involving ~63 individuals, to seismic sounds with received levels ≥170 dB (Table 6.16).

(C) ≥180 dB (rms): Some seals probably were within the 180 dB radius around the operating airguns but were not seen by the observers even though all airgun operations were in daylight. The 180 dB radius for the 4-airgun 280-in^3 source was empirically measured by Greeneridge Sciences as 250 m (Tables 4.7, 5.2). Based on the densities of seals estimated from this project's sighting data under non-seismic conditions, there would be ~24 exposures of seals to ≥180 dB, involving ~23 individuals, under the assumptions listed under (A) above (Table 6.16). The latter estimate far exceeds the zero seals observed directly in areas possibly exposed to ≥180 dB (Table G.6). The difference can be attributed, in part, to the fact that the estimates in Table 6.16 include any seals that

- avoided exposure to ≥180 dB by swimming away from the approaching shallow-hazards survey vessel before entering the 180 dB radius, or
- were present but missed by visual observers because of the inevitable difficulties in sighting small seals in the water in the presence of ice, glare, wave action, etc. [Earlier studies have shown that the detectability of ringed seals in the water diminishes rapidly as distance increases beyond about 50 m—Harris et al. (2001); Moulton and Lawson (2002).]

(D) ≥190 dB (rms): Likewise, based on the densities of seals calculated from our sighting data, we estimate that there would have been 9 exposures of 8 different seals to airgun sounds with received levels ≥190 dB (rms) given the usual assumptions: all seals were below the surface, they showed no avoidance, and the total volume of 4 airguns was 280 in^3 (Table 6.16). However, some of these seals likely would have swum away before the received level reached 190 dB. Others might not have been far enough below the surface to be exposed to ≥190 dB. Also, given the use of a smaller airgun source part of the time, the 190 dB radius sometimes would have been less than the assumed 89 m. Thus, the actual number exposed to ≥190 dB was probably lower than the above estimates.

Aerial Surveys for Cetaceans

Monitoring Effort

Aerial surveys were flown on 23–24 Sept. to "clear" the area out to the 120 dB distance, i.e., to assess the occurrence of bowhead whales within that distance of locations where the *Henry Christoffersen* was about to conduct airgun operations. During the aerial survey on 23 Sept., 45.1 km of transect surveys were flown, of which 35.5 km were flown in good conditions (Bf < 5 and/or sightability ≤ 3). There was one sighting of a bowhead whale during this survey (Fig. 6.2). On 24 Sept., 174.3 km of transect surveys were flown, of which 152.9 km were flown in good conditions. No whales were seen during this survey. Poor weather prevented complete surveys from being flown on either of the days.

Additional aerial surveys were flown by LGL for Shell in the Beaufort Sea during the 26 Aug. through 24 Sept. period. However, in the absence of airgun operations by the *Henry C.* on any dates in September other than 25 Sept., only the surveys on 23–24 Sept. were needed for purposes of "clearing" an area where the airguns were about to be used.

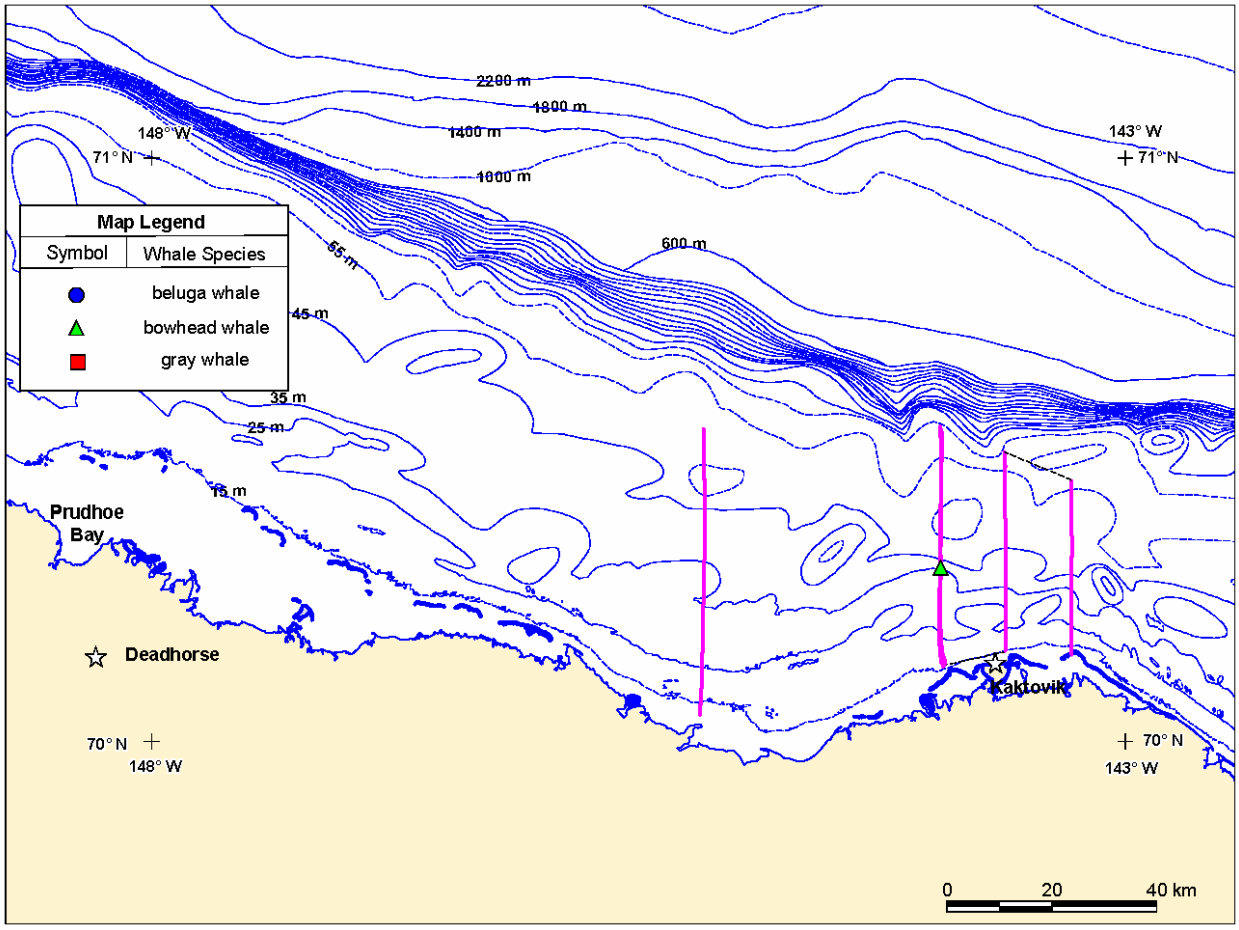

FIGURE 6.2. Aerial survey transects (purple lines) flown by LGL on 23–24 Sept. 2006 in the central Alaskan Beaufort Sea. The third transect from the right was flown twice, on both 23 and 24 Sept.; other transects were flown once.

Distribution of Cetaceans

All whale sightings during LGL/Shell aerial surveys in the Beaufort Sea during late August and September 2006 are shown in Figure 6.3.

In 2006, nearly all bowhead whales sighted during the surveys were found in waters between the 40 m and 100 m depth contours. Only one bowhead sighting occurred shoreward of the 30 m depth contour. Bowhead sightings were concentrated in waters from 40 m to 100 m deep, ~30 to 60 km from shore. Ice conditions during the 2006 field season consisted of a band of pack ice (5 to 40% ice cover) from the shore out to ~20 to 40 km. Beyond this band of ice the waters were open with 0% ice cover. Most bowhead sightings were either at the northern edge of the pack ice in about 5–10 % ice cover, or north of the pack ice in the open water. The most numerous bowhead sightings occurred on 4 Sept. with 13 sightings of 20 bowhead whales, and on 6 Sept. with 14 sightings of 22 bowhead whales. Numbers of sightings during the surveys prior to and after these two varied from 1 to 5. Group sizes throughout the field season varied from 1 to 4, and the predominant activity observed was traveling in a westerly direction.

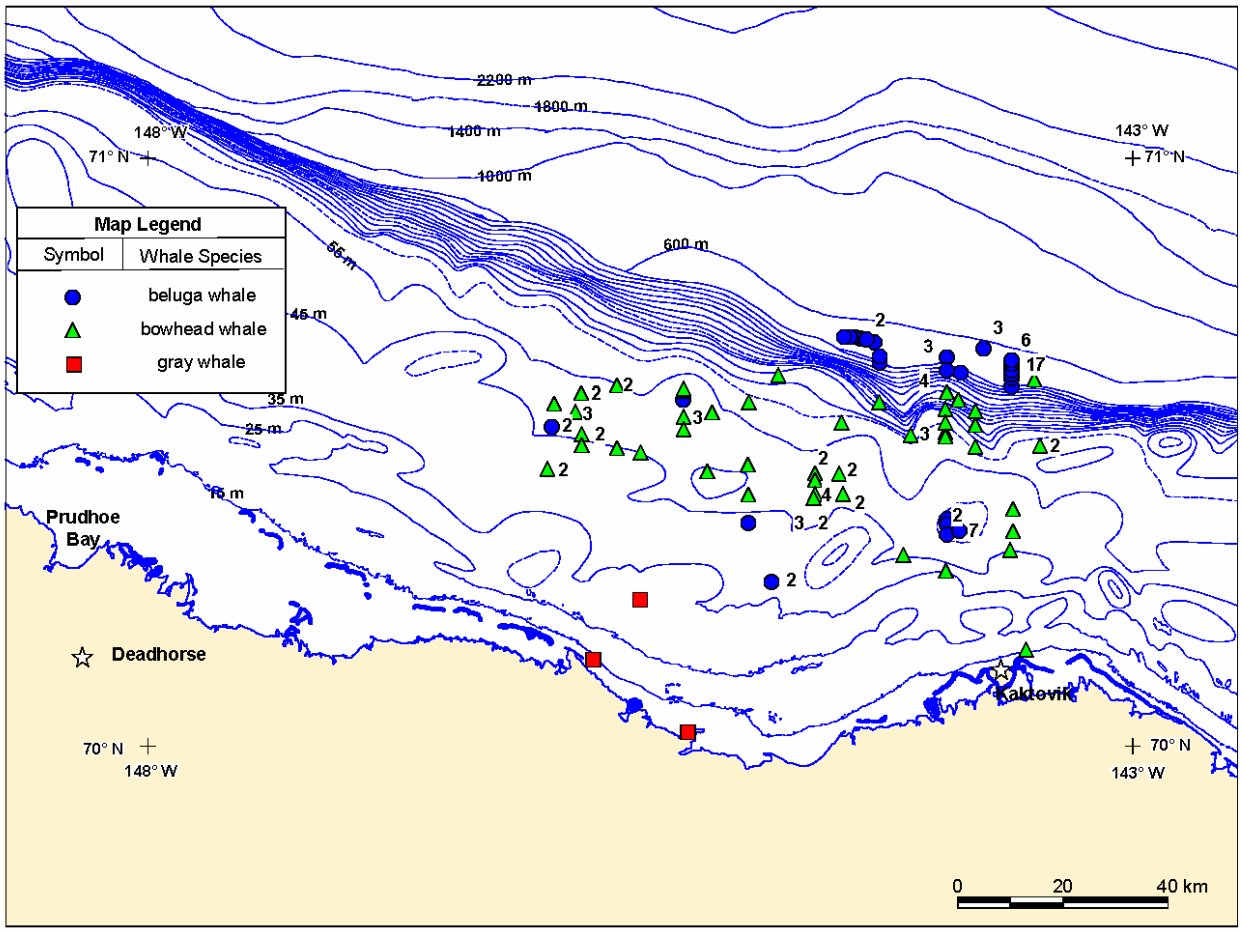

FIGURE 6.3. All whale sightings (on and off transect) in the 2006 SOI shallow-hazards survey area from 26 Aug. to 24 Sept. 2006 based on LGL/Shell aerial surveys. The center of the area of airgun operation on 25 Sept. 2006 is depicted with the ⊗ symbol. Numbers beside symbols indicate group sizes when group size > 1.

Beluga whale sightings were primarily concentrated at the northern end of the transect lines near the 200 m depth contour in 0% ice cover, with a few scattered sightings closer to shore around the 40 m depth contour (Fig. 6.3). The beluga sightings were most numerous on 6 Sept. with 22 sightings of 52 beluga whales. The numbers of sightings during surveys prior to and after 6 Sept. varied from 0 to 4. Group sizes varied from 1 to 7, except for one sighting of 17 beluga whales on 6 Sept. The predominant activity observed was traveling in a southwesterly direction.

Gray whales were seen near the Canning River Delta on three occasions (two on 4 Sept. and one on 14 Sept.). On all three occasions there was only a single whale observed. Of the three gray whales observed, two were traveling and the third was feeding.

Mitigation Measures Implemented

One bowhead whale was sighted on 23 Sept. (Fig. 6.2) but there were no sightings during the 24 Sept. survey. That cleared the area out to the 120 dB distance from the area of planned airgun operations, which proceeded on 25 Sept. No aerial surveys were flown on 25 Sept. due to poor weather conditions.

Estimated Number of Cetaceans Present and Potentially Affected

The three received level criteria that have been specified by NMFS as relevant in estimating cetacean "take by harassment" are as follows:

- 180 dB re 1 μPa (rms), above which there is concern about possible effects on hearing;
- 160 dB re 1 μPa (rms), above which avoidance and other behavioral reactions are likely; and
- 120 dB re 1 μPa (rms), above which displacement of migrating bowhead whales can occur (bowhead mother/calf pairs must be monitored and not exceed three) (NMFS 2006a).

180 dB Criterion.—NMFS (1995, 1999) concluded that noise pulses from a nearby seismic vessel might affect the hearing abilities of baleen whales if received levels exceed 180 dB re 1 μPa rms. The IHA issued for Shell's 2006 seismic program (NMFS 2006a; see Appendix A) called for immediate shutdown if cetaceans were detected within the 180 dB (rms) radius. It is assumed that the received rms pulse levels might have been 180 dB re 1 μPa or more at distances as great as 330 m (Table 5.2B) from the Henry C. The 330 m value is based on the preliminary field measurements and is more protective than the final field measurement of 250 m for 180 dB re 1 μPa (Table 5.2B,C).

MMOs working onboard the *Henry C.* saw no bowhead whales within (or beyond) the 180 dB distance on 8 Aug. or 25 Sept. when the airguns were operating. It is unlikely that an MMO would miss a bowhead within the 180 dB distance if it was at the surface, and even if it were submerged, the MMO probably would have seen the bowhead earlier or later when it did eventually surface. Thus, the estimated number of bowhead whales exposed to sound pulses with received levels ≥ 180 dB re 1 μPa rms is **zero**.

No beluga whales were sighted by MMOs working onboard the *Henry C.* within the 180 dB radius on 8 Aug. or 25 Sept. when seismic activity was underway. It is unlikely that a beluga was present during this time given the rarity of belugas in nearshore waters in this area during summer and autumn.

160 dB Criterion.—NMFS' practice involving impulsive sounds such as seismic has been to assume that a "take by harassment" may occur if cetaceans are exposed to received levels of sound that exceed 160 dB re 1 μPa rms. Takes of this type involve avoidance and other short-term changes in behavior that occur at distances well beyond those where there is any reasonable possibility of injury to the whales (Richardson

et al. 1986, 1995:372ff; Ljungblad et al. 1988; NMFS 1995). We assume that the 160 dB (rms) distance for Shell's 2006 shallow-hazard source may have been as much as 2.22 km (Table 5.2B) from the Henry C.

MMOs working onboard the *Henry C.* saw no bowhead whales within the 160 dB distance on 8 Aug. or 25 Sept. when airgun operations were underway. We have no specific information on the probability that boat-based observers will sight a bowhead that is within 2.22 km of the vessel. However, given that bowhead whales are below the surface a high proportion of the time, it is possible that a bowhead could have been within 2.22 km of the source vessel when the airguns were operating. However, bowheads were unlikely to have been in the area by 8 Aug. Also, the bulk of the bowhead migration in Sept. 2006 was well offshore, some 20 km north of the seismic operations. Thus, it is unlikely that many (if any) bowheads were within 2.22 km of the shallow-hazards survey vessel during the brief period of airgun operations.

No beluga whales were sighted by MMOs working onboard the *Henry C.* within the 160 dB distance on 8 Aug. or 25 Sept. when seismic activity was underway. It is unlikely that a beluga was present during this time given the rarity of belugas in nearshore waters in this area during late summer and autumn.

120 dB Criterion.—In 2006, NMFS specified that it should be assumed that a "take by harassment" may occur if ≥4 bowhead cow/calf pairs are exposed to received levels of sounds that exceed 120 dB re 1 μPa rms. Takes of this type, if they occurred, would involve avoidance and other short-term changes in behavior that sometimes occur at distances far beyond those where there is any reasonable possibility of injury to the whales (Richardson et al. 1986, 1995:372ff; NMFS 1995; Miller et al. 1999). It is assumed that the 120 dB (rms) distance for Shell's 2006 shallow-hazards source was as much as 22.2 km (Table 5.2B) from the Henry C. Again, that value considers all aspects and is based on modeling; the measured value, in the along-trackline direction, was 22.2 km (Tables 4.7, 5.2C).

One bowhead was sighted within the 120 dB distance on 23 Sept., two days prior to airgun operations. That survey provided about 15% coverage of the area within which received levels were expected to be ≥120 dB. It is conceivable that, had aerial surveys been flown on 25 Sept., there might also have been one or more sightings of bowhead whales on that day. Based on the overall distribution of bowhead whales in the 2006 field season, the presence of bowheads is plausible at that date and location. The average detection probability for bowhead whales during late summer/autumn aerial surveys in the central Beaufort Sea is 14.4%, considering all whale activities (Thomas et al. 2002). Based on that, and the one sighting on 23 Sept., the number of bowheads that may have been exposed to the 120 dB re 1 μPa is on the order of **fifteen** bowheads. The calving success of bowheads in 2006 has not been quantified but the proportion of the bowheads that are calves varies between about 2 and 10% of the population (Koski et al. 1993). Even if 2006 was an optimal calving year, it is unlikely that more than 1–2 mother/calf pairs would have been exposed to 120 dB based on the above considerations. These estimates would apply if the bowheads did not avoid the area around the operating seismic vessels before approaching the various radii.

Bowhead whales generally avoid areas around operating seismic vessels, but the avoidance distance varies widely depending on some combination of region, season, and bowhead activity. At some times and places, bowheads generally begin to show active avoidance upon receiving airgun sounds with levels above ~160 dB re 1 μPa rms (Richardson et al. 1986; Ljungblad et al. 1988; Richardson and Malme 1993; G. Miller et al. 2005; LGL unpubl. data). However, migrating bowheads in nearshore

waters of the Alaskan Beaufort Sea in autumn 1996–1998 showed avoidance at lower received levels and longer distances (Miller et al. 1999; Richardson et al. 1999).

SUMMARY OF CHUKCHI AND BEAUFORT SEA MONITORING RESULTS

Vessel-Based Monitoring Effort

Marine mammal observers aboard the *Gilavar* conducted 13,527 km and 1537 h of visual observation, and MMOs aboard the *Kilabuk* conducted 14,058 km and 1251 h of visual observation, together documenting 353 sightings of 442 pinnipeds and 115 sightings of 219 cetaceans. There were numerous sightings of supply and chase vessels within 5 km of each of the observation vessels.

A total of 8213 km and 526 hours of visual observation were conducted aboard the *Henry Christoffersen*, during which 412 sightings of 451 marine mammals were logged. Ringed seals were the most abundant. No sightings were noted during the brief period with airgun operations. Few vessels were sighted during the cruise, and only two of these approached within 5 km of the vessel.

Estimated Number of Marine Mammals Present and Potentially Affected

Based on direct observations from the *Gilavar*, it is estimated that 24 seals were potentially exposed to sound levels ≥180 dB re 1 µPa (rms). Estimates for individual pinnipeds and cetaceans potentially exposed to sound levels ≥160 dB re 1 µPa (rms) are 1317 and 198 respectively.

No animals observed from the *Henry Christoffersen* were potentially exposed to sound levels ≥180 dB re 1 µPa (rms). Based on calculations involving estimated densities of marine mammals, there would have been approximately 180 seals exposed to sound levels ≥160 dB re 1 µPa (rms).

Aerial Survey Effort

On the two days of surveying for mitigation purposes, 219.4 km of transect was flown, of which 188.4 km were flown in good surveying conditions. There was one sighting of a bowhead during these surveys.

AVAILABILITY OF MARINE MAMMALS FOR SUBSISTENCE PURPOSES

SOI exerted a concerted effort to assure that their seismic operations in the Chukchi and Beaufort Seas did not adversely affect subsistence hunting. Representatives of SOI visited rural communities in the spring, months before the project started, to discuss the project with the people who use the Chukchi and Beaufort Seas as their hunting ground. The SOI representatives sought input on how to best accomplish the seismic survey without interfering with subsistence harvests. SOI signed the CAA that outlined strategies of communication and operations to best avoid any impact on subsistence hunting.

In accordance with the CAA, SOI's seismic surveys were arranged to avoid areas of subsistence whaling during the hunting seasons at the various communities. Early in the season Shell's activities in the Chukchi Sea were delayed until after the beluga whale hunt was completed. Later in the year this coordination was effective in preventing the seismic activities from influencing the migration pattern of bowhead whales and affecting the whales' availability. The *Henry C.* worked in the western part of the SOI's Beaufort Sea study area until the whalers to the east, operating from Kaktovik and Cross Island, landed their quotas of whales. The *Henry C.* then moved to the east side of the study area while subsistence whaling was conducted out of Barrow.

All of the vessels involved in the SOI project communicated at least once daily with Communication Centers that were established to relay information between subsistence hunters and seismic and other vessel operators. The locations and activities of each vessel were reported to the Communication Centers. If subsistence hunting was being conducted in an area where seismic or other support activities had been planned, the communicators would have conveyed that information to the vessel personnel and the vessel's work location would have been adjusted accordingly. One instance of this occurred on 6 Sept. when a support vessel, being used to deploy acoustic recorders, turned back when Nuiqsut whalers asked them not to proceed offshore of the Cross Island area. Also, if the whalers had perceived a shift in the bowheads' migration route, the vessels would have been asked to move the operations further away from the subsistence hunting area.

Additional measures that helped reduce the impacts of the Shell operations on subsistence hunting were seasonal accommodations in operations of the *Henry C.,* the decision not to bring the *Gilavar* into the Beaufort Sea in Sept., and the decision to send the *Gilavar* south before many bowhead whales arrived in the Chukchi Sea (where one or two communities planned to conduct fall hunts in 2006). In general, the efforts of SOI to prevent their seismic operations from affecting the availability of marine mammals to subsistence hunters were successful. Kaktovik, Barrow, and Nuiqsut all had successful hunts in 2006.

7. ACKNOWLEDGEMENTS

We thank all of the marine mammal observers (MMOs)—biologists and Inupiat—who participated in the project. They were essential to the completion and success of this endeavor. We thank the captains and crews of the *Gilavar*, the *Jim Kilabuk*, the *Gulf Provider*, the *Peregrine*, and the *Henry Christoffersen* for their support during the cruises. Additionally, we appreciate the help of John Davis and his team at WesternGeco and Mike Schlegel and his team (Geo LLC). We thank the pilots and crew of ERA Aviation for their help with the aerial survey program. We also thank representatives of the National Marine Fisheries Service, U.S. Fish & Wildlife Service, North Slope Borough Department of Wildlife Management, Alaska Eskimo Whaling Commission and Minerals Management Service for their advice and comments during the "open-water meetings" convened by NMFS in April and October 2006 and at various other times. Michael Macrander, Paul Smith, Mark Kosiara, Bob Rosenbladt, Peter Littlewood, Dan Taylor, Travis Allen, Susan Childs, Jason Smith, and Rick Fox at Shell made it easy for us to do our jobs. Additional acknowledgements associated with the acoustical measurements are listed near the end of Chapter 4 in this report.

Distribution and Migration of the Bowhead Whale, *Balaena mysticetus*, in the Eastern North American Arctic

RANDALL REEVES,[1] EDWARD MITCHELL,[1] ARTHUR MANSFIELD,[1] and MICHELE McLAUGHLIN[1,2]

ABSTRACT. Large catches of bowhead whales, *Balaena mysticetus*, were made in the Eastern Arctic of North America, principally in Davis Strait, Baffin Bay, the Lancaster Sound region, Hudson Bay, and southern Foxe Basin, between 1719 and 1915. Initial stock sizes have been estimated as 11 000 in 1825 for the "Davis Strait stock" and 680 in 1859 for the "Hudson Bay stock." The separate identity of these two putative stocks needs confirmation through direct evidence.

Three sets of data were used to evaluate historic and present-day trends in the distribution of bowheads in the Eastern Arctic and to test hypotheses concerning the nature, timing, and routes of their migration. Published records from commercial whale fisheries prior to 1915, unpublished and some published records from the post-commercial whaling period 1915-1974, and reported sightings made mainly by environmental assessment personnel between 1975 and 1979, were tabulated and plotted on charts. Comments made by whalers and nineteenth-century naturalists concerning bowhead distribution and movements were summarized and critically evaluated.

The major whaling grounds were: (1) the west coast of Greenland between ca. 60°N and 73°N, the spring and early summer "east side" grounds of the British whalers; (2) the spring "south-west fishing" grounds, including the northeast coast of Labrador, the mouth of Hudson Strait, southeast Baffin Island, and the pack ice edge extending east from Resolution Island; (3) the summer "west water" grounds, including Pond Inlet, the Lancaster Sound region, and Prince Regent Inlet; (4) the autumn "rock-nosing" grounds along the entire east coast of Baffin Island; (5) Cumberland Sound, a spring and fall ground; and (6) northwest Hudson Bay/southwest Foxe Basin.

The belief of whalers that some segregation occurs within the "Davis Strait stock" cannot be refuted or confirmed on the above evidence. However, the evident predominance of young whales and females with calves in early season catches at the Pond Inlet floe edge and in summer catches well inside Lancaster Sound and Prince Regent Inlet suggests that the route and timing of their migration differs from that of adult males. Apparently most of the whales taken on the autumn "rock-nosing" grounds were large males. The possibility that females and calves circumnavigate Baffin Island, returning south by way of Fury and Hecla Strait, is neither proven nor unproven.

Evaluation of harpoon recoveries did not yield irrefutable evidence of interchange between any presently recognized bowhead stocks; however, this evidence along with recognition of distinctive morphological features does indicate that bowheads exhibit site fidelity to some degree.

The conclusion is that the bowhead population in the Eastern Arctic, severely reduced by whaling activities, continues to occupy much of its former range and follows the same migratory schedule. There is no reliable and consistent evidence of appreciable recovery in absolute abundance of any Eastern Arctic stock.

Key words: bowhead whale, *Balaena mysticetus*, distribution, migration, population identity, whaling history, Davis Strait, Baffin Bay, Lancaster Sound, West Greenland, Hudson Bay, Foxe Basin

RÉSUMÉ. Entre 1719 et 1915, d'importantes prises de baleines boréales, *Balaena mysticetus*, ont été faites dans l'est de l'Arctique nord-américain, tout particulièrement dans le dètroit de Davis, la baie de Baffin, le détroit de Lancaster et la région environnante, la baie d'Hudson et la partie sud du bassin de Foxe. La population initiale du détroit de Davis a été évaluée à 11 000 baleines en 1825 et celle de la baie d'Hudson à 680 individus en 1859. L'existence séparée de ces supposées populations reste à être confirmée au moyen de preuves directes.

Trois sources de données ont été utilisées afin d'évaluer les tendances passées et présentes de la distribution des baleines boréales dans l'est de l'Arctique, ainsi que pour vérifier certaines hypothèses au sujet de la nature, du moment et des itinéraires de leur migration. Les données obtenues à partir de documents antérieurs à 1915, publiés par l'industrie baleinière, de documents publiés et non-publiés sur la chasse non-commerciale à la baleine entre 1915 et 1974 et d'observations rapportées en majeure partie par du personnel responsable de l'évaluation de l'environnement entre 1975 et 1979 furent compilées et utilisées pour tracer des cartes. Des commentaires de baleiniers et de naturalistes du 19ième siècle concernant la distribution et les déplacements des baleines boréales ont été résumés et évalués d'un oeil critique.

Les aires principales de chasse à la baleine étaient: (1) la côte ouest du Groenland environ entre le 60e et le 73e degré nord, correspondant aux pêcheries du "east side" fréquentées par les baleiniers britanniques au printemps et au début l'été; (2) les pêcheries dites du "south-west" fréquentées au printemps, incluant la côte nord-est du Labrador, l'embouchure du détroit d'Hudson, la partie sud-est de la Terre de Baffin et les abords de la banquise s'étendant vers l'est à partir de l'île Resolution; (3) les pêcheries de "west water" fréquentées durant l'été, incluant l'anse de Pond, la région du détroit de Lancaster et l'anse Prince Regent; (4) les pêcheries de "rock-nosing" fréquentées à l'automne le long de toute la côte est de la Terre de Baffin; (5) le détroit de Cumberland, en été et en automné; et (6) le nord-ouest de la baie d'Hudson et le sud-ouest du bassin de Foxe.

Les données précédentes ne permettent pas de confirmer ou de réfuter la croyance des baleiniers voulant qu'il existe une ségrégation au sein de la population du détroit de Davis. Cependant, les prises du début de la saison de chasse aux abords de la banquise de l'anse de Pond et celles faites à l'été bien à l'intérieur du détroit de Lancaster et de l'anse Prince Regent étant pour la plupart des jeunes baleines ou des femelles accompagnées de baleineaux, il est permis de supposer que ces individus accomplissent leur migration en des périodes et suivant des parcours qui diffèrent de ceux des mâles adultes. Il semblerait que la plupart des baleines capturées dans les pêcheries de "rock-nosing" aient été des mâles de forte taille. L'hypothèse selon laquelle les femelles et les baleineaux contourneraient la Terre de Baffin en retournant vers le sud par les détroits de Fury et de Hecla ne peut être ni prouvée ni réfutée. Une évaluation à partir du recouvrement de harpons ne fournit pas de preuve irréfutable d'échanges entre les populations reconnues de baleines boréales; cependant cette évaluation jointe à la reconnaissance de traits morphologiques distinctifs indiquent que les baleines boréales manifestent un certain degré de "homing".

En conclusion, il apparaîtrait que la population de baleines boréales de l'est de l'Arctique, grandement réduite par la chasse, occupe encore une grande partie de son territoire d'origine et suive les mêmes déplacements saisonniers. Il n'existe aucune preuve fiable consistante d'un retour en abondance des populations de l'est de l'Arctique.

INTRODUCTION

The Eastern Arctic, defined here as Hudson Bay and the area north of 60°N latitude between the west coast of Greenland and the vicinity of Melville and Victoria islands (ca. 105°W longitude), once contained a large population of bowhead or Greenland whales, *Balaena mysticetus*. Ross (1974) estimated that no less than 686 bowhead whales were taken by American and Scottish whalers in the Hudson Bay fishery (including Hudson Bay, Foxe Basin, and Hudson Strait) from 1860 to 1915. He (Ross, 1979) also estimated that more than 28 000 were caught by the international fleet (Danish, Dutch, British, German, and American) operating in Davis Strait, Baffin Bay, and the Lancaster Sound region from 1719 to 1911. These substantial catches do not take into account animals killed or mortally wounded but not secured, orphaned calves, and baleen or oil which was lost in accidents, shipwrecks, or fires (Mitchell and Reeves, 1981).

Using mainly published data, Mitchell (1977 MS) made cumulative catch estimates of "initial" size of these two biological populations. For the "Davis Strait stock" he estimated about 6000 in 1729, and for the "Hudson Bay stock" about 680 in 1859 (Allen, 1978, gave 700). His estimate for Davis Strait was subsequently revised to 11 000 whales in 1825 (Mitchell and Reeves, 1981).

Whether the Eastern Arctic population of bowhead whales consists of more than one biological or fishable stock is a moot question. Judgments are based on circumstantial evidence and indirect evidence rather than on direct tracking or tagging data for individual animals. There is little doubt that, as Eschricht and Reinhardt (1861, 1866) emphasized, the bowhead's movements within a stock area are determined principally by ice conditions. The dynamic nature of the sea ice regime means that short- and long-term changes in bowhead distribution might be expected (e.g. Vibe, 1967) and that fragmentation or integration in the aggregate population may occur periodically. Basic patterns of migration, however, appear to remain the same except for differences caused by locally severe or mild ice conditions.

Ross (1974) was unable to decide whether whales winter in Hudson Bay on a regular basis. If they do, the case for a distinct stock there would be strengthened. Mitchell (1977 MS), while recognizing the inconclusive nature of the evidence, proposed two management stocks, one centered in Hudson Bay and Foxe Basin, the other in Davis Strait and Baffin Bay. These two putative stocks are recognized for management purposes by the International Whaling Commission (Allen, 1978). Further consideration of the stock identity question led Mitchell and Reeves (1981) to suggest the possibility that, historically at least, there may have been even more than two bowhead stocks in the Eastern Arctic. This question clearly requires closer scrutiny.

Although several good synthetic appraisals have been made of the bowhead's historic distribution and migration in the Eastern Arctic (Eschricht and Reinhardt, 1861, 1866; Brown, 1868; Gray, 1888; Southwell, 1898; Low, 1906; Ross, 1974), none of these alone is adequate for present management needs. It has been stated that the bowhead population is recovering from the serious depletion caused by commercial whaling and that its distribution remains essentially the same as it was during the nineteenth century (Mansfield, 1971). However, recent systematic surveys of former areas of occurrence have not upheld the view that the population is recovering (Davis and Koski, 1980). Particularly in light of continued whaling activities by Canadian Inuit (Mitchell and Reeves, 1982) and initiatives by oil and gas companies to extract and transport nonrenewable resources throughout much of the Canadian Arctic (Roots, 1980; Stirling *et al.*, 1981), a critical review of available data bearing on bowhead stock identity, distribution, migratory behaviour, and abundance in the Eastern Arctic is needed. The purpose of this paper is to contribute to such a review. [See Appendix A.]

MATERIALS AND METHODS

A search of the literature was made using Cooke and Holland (1978). Whaling and exploration literature was obtained principally from the libraries of McGill University (Montreal), the Arctic Biological Station, and various federal government departments, the National Library of Canada (Ottawa), and the private library of EDM. References that could not be found locally were obtained through interlibrary loan. As noted by Mitchell and Reeves (1981), the Danish colonial records mentioned by Eschricht and Reinhardt (1866:4) are of potential value in assessing the bowhead's movements along the west coast of Greenland. M. Klinowska (written comm., 8 September 1981) has established the fact that these "diaries" are available on microfilm from the Rigsarkivet in Copenhagen. Unfortunately, we had neither the resources to obtain and translate these documents nor the time to examine them for this study. [See Appendix B.]

All available sources were read and indexed for information on bowhead whales, particularly sightings, kills, and migration patterns. Southwell (1898) cautioned concerning the early literature that "too often the vague mentions of 'whales' seen leave the species so uncertain as to be valueless for any useful purpose." He added that "the chief and most reliable information is to be derived from those whose business it is to pursue and capture these animals in their summer haunts." Although we have borne in mind the danger of misidentification, we also have appreciated the fact that, to the British arctic whalers at least, "nothing is a fish but the Greenland whale" (Markham, 1875:38). In writings of arctic whalers it is generally safe to assume that references to "whale" or "fish" mean the bowhead (e.g. Lubbock, 1937). Almost invariably the narwhal or "unicorn" (*Monodon monoceros*) and the white whale or beluga (*Delphinapterus leucas*), the only other cetaceans regularly encountered in heavy ice where bowheads were hunted, are referred to as something other than "fish" or "whale". Bottlenose whales (*Hyperoodon ampullatus*) were sometimes seen and hunted, especially in lower Davis Strait in spring, and killer whales (*Orcinus orca*), often called "gram-

pus'' or ''swordfish'', were occasionally observed along the ice edge at the summer whaling grounds. Again, however, these species are almost always identified by a name or by characteristic features that make it clear they are not bowheads.

The following post journals in the Hudson's Bay Company Archives, Winnipeg, Manitoba, were read and indexed for mention of bowheads: Pangnirtung (1921-1939; 15 journals), Pond Inlet (1921-1939; 16 journals), Blacklead Island (1925-1931; 5 journals), Igloolik (1940; 1 journal), Arctic Bay (1937-1941; 6 journals), Coats Island (1918-1927; 3 journals), Padley (1937-1938; 1 journal), Frobisher Bay (1920-1936; 6 journals), Clyde River (1930-1936; 6 journals), Mansel Island (1930-1932; 3 journals) and Cape Dorset (1913-1941; 10 journals). In addition, a small sample of whaling journals and logbooks was read. This included the 22 logbooks covering the years 1877-1925 in the Stefansson Collection, Dartmouth College, Hanover, New Hampshire, and ''A Journal kept during a voyage to Baffin Bay in the ship Abram of Hull in search of Whales, commencing on the 11th day of March 1839 and ending [October 20, 1839]'', owned by the Manitoba Provincial Archives, Winnipeg.

The ''modern'' (post-1914) data used in this analysis come from various sources. In addition to published accounts and HBC Archives material, we consulted: the files of the Arctic Biological Station compiled by D.E. Sergeant, W. Hoek, and others; AWM's files used in the preparation of his short review on the bowhead's status in the Canadian Arctic (Mansfield, 1971); and reports of environmental assessment surveys conducted by private consulting companies on behalf of the petroleum industry. Sergeant and Hoek have been collecting information on bowheads from sighting cards distributed among personnel working in the Canadian Arctic since the early 1970s. Many of their records, as well as those in Mansfield's files, are from the Royal Canadian Mounted Police (RCMP) game reports, Canadian Armed Forces observers, game and wildlife officers in arctic settlements, pilots, missionaries, icebreaker personnel, scientists, and government representatives. Such records are generally not collected in any systematic fashion, and many are difficult to verify. On the other hand, much of the data from the environmental consulting firms was collected systematically.

It is important to point out that non-English-language literature has not been searched. Nor have we attempted to mine as thoroughly as we might have the English-language literature on bowhead occurrences along the Greenland coast. Thus, records for the Greenland side of Davis Strait and Baffin Bay are conspicuously missing from our charts and tables.

All sightings and kills of bowheads that we indexed, amounting to more than 900 entries, were tabulated and plotted on maps. Records were organized into three categories to reflect the type of source from which they originated and the type of effort used to collect them. The first category covers the period 1615 to 1913, during which extensive whaling and exploration occurred in northern regions (Table 1; Figs. 1,2). These records give a general picture of where and when early (pre-1914) whalers and explorers encountered bowheads in the Eastern Arctic. Tables 2 and 3 and Figure 3 include data for the period 1914 to 1974, from the end of commercial whaling for bowheads in the Eastern Arctic to the approximate beginning of intensive, systematic environmental assessment. Most of the information for this period comes from unpublished data in the Hudson's Bay Company Archives and AWM's files (see Mansfield, 1971), although a number of published records are included. Data from assessment surveys and the Arctic Biological Station sighting report program, spanning the period 1975 to 1979, are presented in Table 4 and Figure 4.

TABLE 1. Occurrence of the bowhead whale in the eastern Canadian Arctic, 1615-1913

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
1	Whale Sound, 77°30'N	1615	VII	5	''a great number''			Bylot, *in* Ellis, 1748:52.
2	Smith Sound	1615	VII		''a great number'', very large			Bylot *in* Ellis, 1748:52.
3	Whale Sound, 77°30'N	1616	VII	4	''great numbers''			William Baffin, *in* Scoresby, 1820:V.1:88.
4	Smith Sound	1616			''an abundance''			William Baffin, *in* Pennant, 1784-87: V.1:clxxxvi.
5	Hudson Strait	1631	VI	22	1			Fox, *in* Ellis, 1748:58-59.
6	Off ''Brook Cobham'' [Marble?] Island, Hudson Bay	1631	VII	28(?)	40 in a pod			Fox, *in* Ellis, 1748:58,68.
7	Off Cape Fullerton, Hudson Bay	1722	VII	9	Many			Scroggs *in* Ellis, 1748:81.
8	Off W coast of Hudson Bay, 64°08'N	1722	VII	15	Many			Scroggs *in* Ellis, 1748:82.
9	Off W coast of Hudson Bay, 64°50'N	1722			A number			Scroggs *in* Ellis, 1748:84.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
10	Roes Welcome Sound	1737	VII	28	Many			Dobbs *in* Ellis, 1748:90.
	"12 leagues above Deer Sound," Hudson Bay	1737	VII		A number		Black whales "of the whalebone kind".	Dobbs *in* Ellis, 1748:91.
	Along W shore of Roes Welcome Sound	1737	VIII	9-12	Many large		Black whales "of the right whalebone kind".	Dobbs *in* Ellis, 1748:[89].
	Off W coast of Hudson Bay, between 55° and 62°15'N	1737			Many		"An abundance" of "black whales."	Dobbs *in* Ellis, 1748:83.
11	Between Cape Southampton and Mansel Island, Hudson Bay	1746	VIII	2		1	Carcass seen floating, with an Eskimo harpoon in it, a thong of walrus hide attached to the harpoon.	Ellis, 1748:144.
12	Off Cape Fry, Hudson Bay, 64°32'N	1747	VII	18	Several		"Sporting" near the shore.	Ellis, 1748:241.
13	Roes Welcome Sound	1747	VII	23	Several			Ellis, 1748:244.
14	In Repulse Bay	1747	VIII	12-13	"a great many"			Ellis, 1748:270.
15	Along W shore of Hudson Bay	1747(?)	Late summer		Very large numbers			Ellis, 1748:322.
16	Uivak, Labrador	1772				1	Carcass found on shore or killed.	Haven, 1773:3.
17	Comfort Harbour, 7 mi S of Nain, Labrador, near 56°30'N	1773	II			1 (est.)	Carcass found covered with 1 fathom of snow and ice. It was "middling size", 64 ft (est.).	Anon., 1835:96-104.
18	Hebron [Kangertluksoak], NE Labrador coast	1771				2 killed		Taylor, 1974.
19	Saglek, NE Labrador coast	1771				1 killed		"
20	Nachvak, NE Labrador coast	1771				2 killed		"
21	Hebron [Kangertluksoak], NE Labrador coast	1772				2 killed		"
22	Nain area, NE Labrador coast [a barren seaward island in Nain area]	1773	II	16		1	Carcass found.	"
23	Hopedale [Arvertok], NE Labrador coast	1773	IV	17		1	This dead whale may have been mortally wounded in another area.	"
24	Nachvak, NE Labrador coast	1773				1 killed	"only one killed on whole coast" in 1773.	"
25	Hopedale [Arvertok], NE Labrador coast	1774				1 killed		"
26	Coast of Labrador N of Nain, NE coast	1775				6 killed		"
27	Near Okak, NE Labrador coast	1776	X	21	"some"			"
28	Near Okak, NE Labrador coast	1776	XI	11		1 struck	Lost.	"
29	Near Okak, NE Labrador coast	1776	XI	13		1 struck	Lost.	"
30	Near Okak, NE Labrador coast	1776	XI	27		2 struck	Lost.	"
31	Uivak and Kivalek, Okak area, NE Labrador coast	1776	8 XI to 4 XII		7		7 whales (total) were sighted during this time in the Okak area, 2 of which were struck but lost on 27 XI 1776, one on 11 XI, another on 13 XI, while 2 whales were seen 4 XII. Presumably these are included in the total of 7 and are described in above and following entries.	"
32	Near Okak, NE Labrador coast	1776	XII		4		Pursued but not caught.	"
33	Nain area, NE Labrador coast [a seaward island in Nain area]	1776				1	This drift whale may have been mortally wounded in another area.	"
34	Coast of Labrador N of Okak	1776				1 killed		"
35	Near Kivalek, Okak area, NE Labrador coast	1777	XII	7	2			"
36	Hebron [Kangertluksoak], NE Labrador coast	1777				1 killed		"
37	Near Okak, NE Labrador coast	1778	XI	3		1 killed, 60 ft long	With 5 harpoons which had 10 sealskin pokes attached.	"
38	Hopedale [Arvertok], NE Labrador coast	1778				1 killed		"
39	Saglek, NE Labrador coast	1778				1 killed	"Baleen whale".	"

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
40	Khernertut, Okak area, NE Labrador coast	1779	XI	21	2	1 killed	2 whales were sighted, of which 1 was killed with 3 harpoons.	Taylor, 1974.
41	Mouth of Okak Bay, NE Labrador coast		XI	28	"More"	1 killed	"More" whales were sighted, one of which was killed.	"
42	Nachvak, NE Labrador coast	1779				2 killed		"
43	Hebron [Kangertluksoak], NE Labrador coast	1779				2 killed		"
44	Hopedale [Arvertok], NE Labrador coast	1779				2 killed		"
45	Nain area, NE Labrador coast	1780	I	9		1 apparent kill	A dead whale with 3 seal skin pokes was seen driven out to sea.	"
46	Near Okak, NE Labrador coast	1780	X	27	Several		"Too early" for the Eskimos to be prepared for hunting.	"
47	3 leagues from Okak, NE Labrador coast	1780	XI	20		1	Found in a decayed state: "only good for lamps and dogs." May have been mortally wounded in another area.	"
48	Kivalek, near Okak, NE Labrador coast	1780	XI	27	"some"			"
49	Hebron [Kangertluksoak], NE Labrador coast	1780	XII	27		2 killed		"
50	Hopedale [Arvertok], NE Labrador coast	1780				1 attempted kill	Pursued but lost.	"
51	Nachvak, NE Labrador coast	1780				1	Found with "all his bones and fins."	"
52	Near Sungilik, Okak area, NE Labrador coast	1781	XI	7		1 struck	With 1 harpoon and an attached sealskin poke, but escaped.	"
53	Kivertlok, Okak area, NE Labrador coast	1781	XI - 28 XI		"plenty"	6 struck	3 were harpooned but lost, while 3 others were struck without harpoons penetrating the skin (one of these whales may already be described above, 7 XI 1781, struck near Sungilik, Okak area).	"
54	Near Okak, NE Labrador coast	1781	XI	28		1 killed		"
55	Nachvak, NE Labrador coast	1781				2 killed		"
56	Saglek, NE Labrador coast	1781				2 killed		"

110	Uivak, near Okak, and Okak, NE Labrador coast	1795			12	"some" killed	12 whales were sighted, "some found dead and some caught."	Taylor, 1974:33; Brice-Bennett, 1980 MS.
111	Nain area, NE Labrador coast ["on the coast"]	1795				2	Carcasses found.	Brice-Bennett, 1980 MS.
112	Saglek, NE Labrador coast	1796				1 killed	The only one killed on the whole coast this year.	Taylor, 1974; Brice-Bennett, 1980 MS.
113	Okak, NE Labrador coast	1796			some	Attempted kills		Brice-Bennett, 1980 MS.
114	Nachvak, NE Labrador coast	1797				Some	Nachvak Eskimos were "the only people who got whales."	"
115	Near Okak, NE Labrador coast	1799	Spring			1 killed, young		"
116	Okak and Kivalek, near Okak, NE Labrador coast	1799	Spring		Some	Attempted kills	The Eskimos could not approach near enough to the whales to harpoon any.	"
117	Near Okak, NE Labrador coast	1800	XI			1 killed, very large		"
118	Along coast N of Okak, NE Labrador coast	1800				5 killed		"
119	Nachvak, NE Labrador coast	1801				Several killed		"
120	Saglek, NE Labrador coast	1801				Several killed		"
121	Coast N of Okak, NE Labrador coast	1802				3 killed		"
122	Coast N of Okak, NE Labrador coast	1803	Autumn			5 killed		"
123	Coast N of Okak, NE Labrador coast	1804	Spring			2	Carcasses found.	"
124	Near Hopedale, NE Labrador coast	1804	VIII-IX			1	Carcass found.	"
125	Island, Nain area, NE Labrador coast	1805	I			1	Carcass found.	"
126	Kivalek Bay, Okak area, NE Labrador coast	1805	XI	16-17	Several	Attempted kill		"
127	Near Igloksoaktaligarsuk Island, Nain area, NE Labrador coast	1806	VII	10		1 killed, young, 20 ft (est.)	Possibly a right whale (*Eubalaena*)?	"
128	Churchill River area, Hudson Bay					3 killed		Hearne, 1795 *in* Preble, 1902:39.
129	Nain or Hopedale, Labrador	1806	Fall-early winter			1 killed	Saved mission Eskimos from famine.	Anon., 1835:281.
130	Nachvak area, Labrador	1811	VII	16		1	Large carcass found by Eskimos stranded on shore, in a very decayed state. It occupied a space 30 ft (est.) in diameter.	Kohlmeister and Kmoch, 1814:26-27.
132	73°37′N, 77°25′W near Cape Liverpool, N Bylot Island	1818	IX	1		1	Skeleton found 500 yd. (est.) above the high-water mark.	Ross, 1819:179.
133	73°30′00″N 77°24′09″W, Coast of NE Bylot Island, Lancaster Sound	1818	IX	2		1	Skeleton found on beach.	Fisher, 1821:74-75.
134	Near 63°59′29″N 61°26′10″W, off Hall Peninsula, SE Baffin Island	1819	VI	25	2		The first seen on the voyage.	Fisher, 1821:31.
135	63°59′29″N 61°26′10″W (chronometer), off Hall Peninsula, SE Baffin Island	1819	VI	26	1			Fisher, 1821:33.
136	160 mi (est.) S of entrance to Lancaster Sound	1819	VII	29	A number		The first whales sighted since the ship entered Baffin Bay at 70°N.	Fisher, 1821:56; Anon., 1821:22.
137	In Baffin Bay near entrance to Lancaster Sound	1819	VII	30	50 (est.)		During a 4-hour afternoon watch. Whales moving north and northwest.	Fisher, 1821:58; Anon., 1821:22.
138	73°31′16″N 77°44′41″W. In Possession Bay, NW coast Bylot Island, Lancaster Sound	1819	VII	31	A number		Seen close to shore; Fisher thought they would run aground.	Fisher, 1821:63; Anon., 1821:22.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
139	73°31′16″N 77°44′42″W. Stream-bank in Possession Bay, NW coast Bylot Island, Lancaster Sound	1819	VII	31 (ca.)		?	Whale bones found.	Fisher, 1821:60.
140	Near entrance to Navy Board Inlet	1819	VIII	1	A number			Fisher, 1821;Anon, 1821:25.
141	73°31′16″N 80°30′ to 82°W. Vicinity of mouth of Navy Board Inlet	1819	VIII	2	Large numbers		30-40 whales per watch were sighted, moving in pods like porpoises, diving and surfacing in concert. Traveling west.	Fisher, 1821:66; Parry, 1821:31.
142	At 86°56′W, western Lancaster Sound	1819	VIII	4	20-30			Fisher, 1821:70.
143	Lancaster Sound [western] or northern Prince Regent Inlet	1819	VIII	6	Several			Fisher, 1821:74.
144	Baffin Bay, 77°N	1819	VIII	8	1			Lubbock, 1937:211.
145	Near 72°13′N 90°29′W, central Prince Regent Inlet	1819	VIII	9	Large numbers			Fisher, 1821:80-81; Parry, 1821:42; Anon., 1821:31.
146	72°37′N 74°13′W, off entrance of Coutts Inlet, NE Baffin Island coast	1818	IX	5	2		Several very large icebergs in the area.	Ross, 1819:192.
147	70°40′N 68° W, near Agnes Monument, NE Baffin Island coast	1818	IX	10	Some large		Swimming rapidly southward. Some icebergs with loose ice in vicinity.	Ross, 1819:200.
148	Okak, NE Labrador coast	1812	Mid-I			1	Carcass found.	Brice-Bennett, 1980 MS.
149	Near Okak, NE Labrador coast	1813			Several	1 killed		"
150	Near Okak, NE Labrador coast	1816	Autumn			1 killed		"
151	Near Okak, NE Labrador coast	1818	X-XI			1 killed		"
152	Frozen Strait; Duke of York Bay	1821	VIII	17	"A great number"		"Playing about the beach."	Parry *in* Southwell, 1898:410; Parry, 1824:42; Lyon, 1824:48.
153	Near Okak, NE Labrador coast	1820	XII	4		1 killed		Brice-Bennett, 1980 MS.
154	In Repulse Bay	1821	VIII	22	"Whales seen"			Parry *in* Southwell, 1898:410; Parry, 1824:52.
155	Nachvak, NE Labrador coast	1821				1 killed		Brice-Bennett, 1980 MS.
156	Off Rouse Island, Hurd Channel	1821	VIII	28	3		"Probably" heading for Roes Welcome Sound.	Parry *in* Southwell, 1898:410; Parry, 1824:69.
157	Hebron [Kangertluksoak], NE Labrador coast	1821				1	Carcass found.	Brice-Bennett, 1980 MS.
158	Off E entrance to Fury and Hecla Strait.	1822	VIII	5(ca.)	Some			Parry *in* Southwell, 1898:410; Parry, 1824:301.
159	On the coast, Nain area, NE Labrador coast	1823	Autumn			1 (ca.38 ft)	Carcass found.	Brice-Bennett, 1980 MS.
160	Near Okak, NE Labrador coast	1823				1 (ca.56 ft.)	Carcass found.	"
161	Saglek, NE Labrador coast	1823				1 (ca.56 ft)	Carcass found.	"
162	Okak Bay, NE Labrador coast	1825			1			"
163	Hopedale area, NE Labrador coast	1827	VII			1	Carcass found with blubber and baleen intact.	"
164	Near 73°33′N 74°42′W, 13 leagues E of Possession Bay, S Lancaster Sound coast	1829	VIII	6		1	Carcass with blubber and baleen removed was seen.	Ross, 1835:88.
165	Possession Bay area, 73°50′N, Lancaster Sound	1829	VIII	7		1+	The "krang" of a whale, with some blubber, was retrieved from the water.	Ross, 1835:93.
166	Near 73°50′N 77°W, Lancaster Sound	1829	VIII	8		Some	The "remains of whales" were "still seen."	Ross, 1835:95.
167	Fury Point, W side of Prince Regent Inlet, 72°42′N 92°13′W	1829	VIII	14	Several			Ross, 1835:111.
168	Off Hazard Inlet, SW Prince Regent Inlet	1829	VIII	15	Many		"Many whales of a light colour came close to us [the *Victory*]", seemingly indifferent to the ship's presence. There was close-packed ice in the bays and inlets of southern Somerset Island, and heavy ice in northern Gulf of Boothia.	Ross, 1835:115.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
169	Near [somewhat S of] 71°59'N 93°32'W, NW Gulf of Boothia	1829	VIII	17	Many		Many whales were seen near a large rock, part of a reef extending into northwestern Gulf of Boothia. The whales seemed to be feeding and "enjoying themselves in perfect security." 1 large whale approached the ship. Inlets were filled with ice, and there were bergs and heavy ice in Gulf of Boothia.	Ross, 1835:119.
170	Near 70°59'N 93°02'W, NW Gulf of Boothia	1829	VIII	20	Many		Seen, together with some seals in close-packed, drifting ice with several leads of open water.	Ross, 1835.
171	Near 73°12'N 89°41'W. E side of Prince Regent Inlet	1819	VIII	13	Large numbers			Fisher, 1821:89.
172	73°12'N 90°34'W. Off NE coast Somerset Island	1819	VIII	16	Large numbers			Fisher, 1821:91.
173	Mouth of Wellington Channel, Barrow Strait	1819	VIII	22	5-6		Icebergs in area.	Fisher, 1821:93; Anon., 1821:112, 33-34; Parry, 1821:51.
174	71°30'N 71°15'W, near Cape Adair, NE coast Baffin Island	1820	IX	3		1	Whale bones found on coast.	Fisher, 1821.
175	Davis Strait, probably central or NE coast of Baffin Island	1820	IX	16	Several			Fisher, 1821:286.
176	Pond Inlet land-floe	1823	VII	27			Remains of hundreds of flensed whales seen along the Pond Inlet floe edge.	Lubbock, 1937:254.
177	Lancaster Sound	1823	VII	8-day period	Large numbers	Many	During an 8-day period there was a large run of whales. Several ships took 12+ whales, 1 or 2 ships took 15 whales each, 1 ship got "full" (36 whales?).	Lubbock, 1937:254-255.
178	Lancaster Sound	1823	VII		"Vast" numbers			Lubbock, 1937:254.
179	Lancaster Sound	1823	VII			Many	Many hundreds of flensed whales were left along the floe edge in Lancaster Sound and Baffin Bay.	Lubbock, 1937:254-255.
180	Near Duke of York Bay, northern Southampton Island	1824			Many			Lyon, *in* Preble, 1902:39.
181	Off Port Bowen, 73°14'N 88°55'W, E side Prince Regent Inlet	1825				1 killed	"Payable" size.	Markham, 1874:250.
182	"Southwest fishing", SE Baffin Island area, mouth of Hudson Strait, or coast of northern Labrador	1826	VI	26 (up to this date)		5-6	The *Brunswick* took 5 large whales and found 1 large dead whale, baleen of 10 ft 11 in. length.	Lubbock, 1937:262.
183	"West water", S of Cape Searle, central E Baffin Island coast	1826	VIII		Large numbers			Lubbock, 1937:263.
184	Davis Strait, between 60 mi NW of N end Disko Island, Greenland, and 68°37'N ca. 63°W	1827	II	1	Several		In holes of water; heavy ice.	Lubbock, 1937:266.
185	Davis Strait, between 60 mi NW of N end Disko Island, Greenland, and 68°37'N ca. 63°W	1827	II	2		1 killed	Baleen of 9 ft 4 in. length; in very heavy ice.	Lubbock, 1937:266.
186	Davis Strait, between 60 mi NW of N end Disko Island, Greenland, and 68°37'N ca. 63°W	1827	II	17		2 struck	Very heavy ice.	Lubbock, 1937:267.
187	Between 68°37'N ca. 63°W and 63°N 61°30'W, off SE Baffin Island, probably off mouth of Cumberland Sound	1827	III		Many		Solid ice 5 mi around.	Lubbock, 1937:268.
188	62°N 61°W, ca. 120 mi E of mouth of Frobisher Bay	1827	IV	30	2	1 struck/ lost		Lubbock, 1937:271.
189	Near 62°N 61°W, ca. 120 mi E of mouth of Frobisher Bay	1827	V	3-6		Some killed		"
190	Near 62°N 61°W, ca. 120 mi E of mouth of Frobisher Bay	1827	V	11		4 killed		"

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
191	Near 62°N 61°W, ca. 120 mi E of mouth of Frobisher Bay	1827	V	12		2 killed		Lubbock, 1937:271.
192	Davis Strait, "Southwest fishing", SE Baffin Island coast, mouth of Hudson Strait, or northern Labrador coast.	1827	V-VI			11 killed	170 tons of oil.	Lubbock, 1937:272.
193	Off Cape Searle, SE coast of Baffin Island	1828	IX	21		1	Carcass found.	Lubbock, 1937:275
194	South-East Bay [Disko Bay]	1829	IV	1-7		1 killed		Lubbock, 1937:277.
195	"West water" near 73°54'N at mouth of or in Lancaster Sound	1829	VII	14		1 killed	11 ft 3 in. baleen.	Lubbock, 1937:278.
196	Off Cape Coutts, NE coast Baffin Island	1830	IX	6		1	Carcass found.	Lubbock, 1937:282.
197	Southward of Cape Searle, SE coast of Baffin Island	1831	VIII	29		1 killed	Lost.	Lubbock, 1937:286.
198	Southward of Cape Searle, SE coast of Baffin Island	1831	VIII	29		1 killed	9 ft 8 in. baleen; 44 butts of blubber.	"
199	Southward of Cape Searle, SE coast of Baffin Island	1831	VIII	29		1 killed		"
200	Brodie Bay, NE coast of Baffin Island	1835	VIII		Many		Whalers kept away by the setting in of "young ice."	Anon. 1836:6.
201	Off Cape Broughton, northern end of Broughton Island, SE coast of Baffin Island	1835	IX	Last 2 weeks	Many	4 struck/ lost	Crew of *Viewforth* chased whales every day, striking but losing 4 (each weighing 15 to 20 tons).	Anon., 1836:8.
202	Southward of Cape Searle, SE coast of Baffin Island	1835	XI	11	"A great many"		"Playing" around the *Viewforth*. Belugas and narwhals seen among the bowheads.	Lubbock, 1937:309.
203	Southward of Cape Searle, SE coast of Baffin Island	1835	XI	13	Many			Lubbock, 1937:310.
204	Along NE coast of Baffin Island, in or N of Home Bay	1835	XI	29		2	Carcasses picked up by the *Abram*; these whales appeared to have died of disease; no wounds evident.	Lubbock, 1937:312.
205	Off Cornelius Grinnell Bay, in 62°57'N, SE coast Baffin Island ca. 4 mi offshore (est.)	1835	XII	27	1		Heard blowing in heavy ice.	Lubbock, 1937:317.
206	Okak, Labrador	1835 (ca.)			"Some"			Anon., 1835:122.
207	Near 70°59'N 93°02'W, along NW coast of Gulf of Boothia.	1829	VIII	21	2 large		Near shore, in heavy, thick ice with some leads of open water.	Ross, 1835:125.
208	Near 70°59'N 93°02'W, along NW shore of Gulf of Boothia	1829	VIII	22	1 large		In thick ice with some leads of open water.	Ross, 1835:126.
209	Near 70°36'N 92°06'W, along NW shore of Gulf of Boothia	1829	IX	2	1 small		In pack ice.	Ross, 1835:140.
210	Near 70°55'N 92°06'W, along NW shore of Gulf of Boothia	1829	IX	5	2		In heavy pack ice with icebergs; open water between shore and the pack.	Ross, 1835:142.
	N side of Elizabeth Harbour, NE coast of Boothia Peninsula	1829	IX	8		Some	Numerous bones of whales were found in or near the remains of Eskimo summer houses. These remains were "of so old a date as to show it was long since this part of the shore had been inhabited."	Ross, 1835:146.
212	Near Fury Beach, SW shore of Prince Regent Inlet	1832	VIII	23	1		Heard but not seen. There was thick, unbroken ice everywhere.	Ross, 1835:660.
213	Off Prince Leopold Island, near 73°56'N 90°W, in SE Barrow Strait	1832	IX	1	4		Prince Regent Inlet, Barrow Strait and Lancaster Sound were an "unbroken field of ice."	Ross, 1835:665.
214	Hebron [Kangertluksoak], NE Labrador coast	1834				1 attempted kill		Brice-Bennett, 1980 MS.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
215	Near Okak, NE Labrador coast	1835	Mid-XII			1	Carcass found; carried out to sea by swell.	Brice-Bennett, 1980 MS.
216	Near Cape Graham Moore 72°51′N 76°04′W, in Pond Inlet mouth	1849	VII	9	2 (female +calf)	1 killed, large female	First whales seen by Goodsir in Pond Inlet area. Female had 11 ft baleen.	Goodsir, 1850:66-69.
217	Off Pond Inlet, in Baffin Bay	1849	VII	10-20		"Occasional" small whale killed		Goodsir, 1850:76.
218	Off Pond Inlet	1849	VII	10-20	Some		"More or less plentiful."	Goodsir, 1850:75.
219	Pond Inlet area, 10 mi away	1849	VII	10-20	Many		They did not enter Pond Inlet very far. For some time "shoals" of narwhals had been seen before the appearance of the bowheads.	Goodsir, 1850:77-78.
220	Off mouth of Pond Inlet	1849	VII	10-20		1 killed	By a Kirkaldy whaler during the "run" of whales.	Goodsir, 1850:80.
221	Off mouth of Pond Inlet	1849	VII	10-20		1 killed, large	10-11 ft baleen; taken by the *Advice*.	"
222	Off mouth of Pond Inlet	1849	VII	10-20		1 killed	During the "run" of whales.	Goodsir, 1850:80.
223	Off mouth of Pond Inlet	1849	VII	10-20		2-3 attempted kills	The *Advice*.	Goodsir, 1850:85.
224	Off mouth of Pond Inlet	1849	VII	10-20		1 struck/ lost, large	The *Advice*.	Goodsir, 1850:85-86.
225	Off mouth of Pond Inlet	1849	VII	10-20	"Hundreds"		Whales were "pouring round the point of ice, and apparently running in towards the bay [Pond Inlet], almost in hundreds." It seems the whales did not actually enter Pond Inlet.	Goodsir, 1850:88; Lubbock, 1937:351.
226	Near Button Islands, 10 mi N (est.) offshore, E end Hudson Strait	1836	I	5	Several		Heavy ice.	Lubbock, 1937:318.
227	Just S of Pond Inlet	1838 (ca.)			"Several hundreds"		Heading north "in a continuous flock", apparently for the mouth of Lancaster Sound.	Brown, 1868:540.
228	Cumberland Sound	1846			Numerous large			Lubbock, 1937:346.
229	Vicinity of Chesterfield Inlet, NW Hudson Bay, ca. 63°N	1846	VII	13	Over 12, some very large			Rae, 1850:27.
230	Roes Welcome Sound, ca. 64-65°N	1846	VII	19-20	"A great many"			Rae, 1850:32.
231	Labrador coast	1848				1 attempted kill	By netting. The whale entered the net during the evening and carried it off.	Clark, 1887:248.
232	Off Pond Inlet and Coutts Inlet, NE coast of Baffin Island	1849	VII (ca.)			6 killed		Barron, 1895:7; Lubbock, 1937:351.
233	Off N side of Scott Inlet, NE coast of Baffin Island	1849	VII			Some		Barron, 1895:8; Lubbock, 1937:351.
234	Off Home Bay, NE coast of Baffin Island	1850	IX		Pod		This pod of whales described as "a run of whales."	Barron, 1895:12.
235	Off Home Bay, NE coast of Baffin Island	1850	IX			3 killed		Barron, 1895:12-13.
236	Off Cape Hooper, NE coast of Baffin Island	1850	End of season			14-21 killed	7 whalers took 2-3 whales each.	Lubbock, 1937:353.
237	Between 71°55′N 66°55′W and 70°44′N 63°44′W, 75 mi (est.) off NE Baffin Island coast, Cape Christian area	1851	III		2		In leads in the opening pack ice.	Kane, 1854:390.
238	Near 69°46′N 63°06′W, off Henry Kater Peninsula, NE Baffin Island coast	1851	IV	25	1			Kane, 1854:357.
239	Off Cape [Henry] Kater, SE tip of Henry Kater Peninsula, NE Baffin Island coast	1851	VII	20	1		Apparently it was unusual to see whales this far south at this time of year.	Barron, 1895:25.
240	Off Blacklead Island, Cumberland Sound	1851	IX			1 killed, large		Barron, 1895:27.
241	Off Blacklead Island, Cumberland Sound	1851	IX	Late in month		1 killed	Cut whale loose after capture.	Lubbock, 1937:26.
242	Cumberland Sound, inshore among bay ice	1851	IX	End of month	A number			Barron, 1895:29.
243	Near Neubuyan, Cumberland Sound	1852	Spring			A number killed, small		Lubbock, 1937:357.
244	Near Neubuyan, Cumberland Sound	1852	IX	Late		1 killed, small		Barron, 1895:41; Lubbock, 1937:357.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
247	Off Agnes' Monument, 2 mi SE of Cape Christian, NE coast of Baffin Island	1852	IX			4 killed	Severe weather caused 3 killed whales to break adrift from the ship and be lost.	Barron, 1895:36-37; Lubbock, 1937:356.
248	Off Niatlik [Niante?] Cumberland Sound	1852	IX	Late	A number		"Making a rapid passage southward."	Barron, 1895:43.
250	Home Bay, NE coast of Baffin Island	1852				1 killed		Lubbock, 1937:356.
251	Off Coutt's Inlet and Scott Inlet, NE coast of Baffin Island	1853	VII (ca.)			5 killed	The *Truelove* saw more whales after these 5 as they went south to Cape Dyer but did not get any.	Barron, 1895:50-51.
252	Off Pond Inlet, S side	1853	Summer		Several	1 struck/lost	*Truelove* late for the Pond Inlet whaling, but found an opening close to land on the south side and saw several whales, striking one.	Barron, 1895:50.
253	Off Home Bay, NE coast of Baffin Island	1854	VI (ca.)		A number			Barron, 1895:55.
254	Eclipse Sound	1854			"Plenty"	2 killed	*Eclipse* found Pond Inlet free of ice and went through it to discover Eclipse Sound. "Plenty of whales" were seen in the sound, but the ice was so full of holes and rotten that the ship could not get near them.	Barron, 1895:57.
255	Hudson Strait	1855	VIII	3		1 killed		Ferguson, 1938:182.
256	Foxe Channel	1855	VIII	31		2 killed		"
257	Cumberland Sound	1856	II			2 killed	Unusually mild weather.	Lubbock, 1937:363.
258	Cumberland Sound	1856	II		"Great numbers"		Formation of young ice prevented the approach of whalers.	Lubbock, 1937:363.
259	Off Marble Island, Hudson Bay	1856	VI	3		1 killed		Ferguson, 1938:187.
260	Off Marble Island, Hudson Bay	1856	VI	Mid-month		2 killed		"
261	Off Pond Inlet	1856	VII (ca.)			Several killed		Barron, 1895:72.
262	Off Pond Inlet	1856	VII (ca.)			4 killed	*Truelove* captured these whales before coming to the land floe off Pond Inlet.	"
263	Off Pond Inlet, at land floe edge	1856	VII (ca.)			4 killed	*Truelove* captured these whales after making fast to the land floe off Pond Inlet.	"
264	Off Pond Inlet, off land floe	1856	VII (ca.)			1 killed		Barron, 1895:73.
265	Off Pond Inlet, off land floe	1856	VII (ca.)			2 killed		"
266	Off Pond Inlet, off land floe	1856	VII (ca.)			1 killed	In loose ice.	Barron, 1895:73; Lubbock, 1937:364.
267	Off Pond Inlet, off land floe	1856	VII (ca.)			1 killed		Barron, 1895:73.
268	Off Pond Inlet, at the land floe	1856	VII			Large numbers killed	Whalers made fast to the land floe at Pond Inlet took large numbers of whales, some taking 6 or 7. Apparently the whales were travelling in "runs."	Barron, 1895:72.
269	Off Marble Island, Hudson Bay	1856	Mid-VI			4 killed		Ferguson, 1938:187.
270	Off Southampton Island, northern Hudson Bay	1856	Mid-VIII			2 killed		Ferguson, 1938:187-188.
271	S side of Home Bay, NE coast of Baffin Island	1856	IX (ca.)		A number			Barron, 1895:74.
272	Off Cape Hooper harbour, NE coast of Baffin Island	1856	X		A number			Barron, 1895:76.
273	Off Pond Inlet	1856				1 killed	In loose ice.	Lubbock, 1937:364.
274	65°01′N 55°20′W 100 mi (est.) off W Greenland coast	1857	VII	28	1			M'Clintock, 1863:112.
275	Off Scott Inlet, NE coast of Baffin Island	1857	VIII (ca.)		A few		Fired at 2 or 3 but missed.	Barron, 1895:85.
276	Off Niatlik [Niante?], S side Cumberland Sound	1857	X (ca.)		2		Travelling south at a rapid rate.	Barron, 1895:88; Lubbock, 1937:368-69.
277	Near 69°N 59°W, 150 mi (est.) off Cape Hooper, NE coast of Baffin Island	1858	III	9	1			M'Clintock, 1863:123.
278	68°17′N 58°20′W (est.), 100 mi (est.) off Broughton Island, NE Baffin Island coast	1858	IV	2	2			M'Clintock, 1863:125.
279	67°18′N 58°17′W, 75 mi (est.) off Cape Dyer, NE coast Baffin Island	1858	IV	6	1			"

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
280	63°41′N 58°49′W, 100 mi (est.) off entrance to Cumberland Sound	1858	IV	23	1 large			M'Clintock, 1863:126.
281	75°0′N 78°46′W, off E coast Devon Island	1858	VII	11	1			M'Clintock, 1863:129.
282	74°02′N 82°00′W, off mouth of Navy Board Inlet	1858	VII	17	2		In very loose ice.	M'Clintock, 1863:130.
283	Off Agnes' Monument, 2 mi SE of Cape Christian, NE coast of Baffin Island	1858	VII (ca.)		Several			Barron, 1895:96.
284	72°48′N 76°30′W (est.), off entrance to Pond Inlet	1858	VIII	4	Several			M'Clintock, 1863:131.
285	72°48′N 76°39′W, 3 mi SE of Cape Graham [Moore], SE tip of Bylot Island	1858	VIII	5	1			"
286	Between 72°47′N 77°09′W and 72°48′N 76°39′W, off E coast of Bylot Island	1858	VIII	1-5	Very numerous			"
287	Off Nugumut, Cumberland Sound	1858	IX (ca.)	Late	A number			Barron, 1895:98.
288	Above Nugumut, Cumberland Sound	1858	IX (ca.)	Late	Several		Travelling "up" Cumberland Sound at great speed. "If one rose to the surface it only gave one blast, and the next time it would be a couple of miles off."	Barron, 1895:101.
289	Above Nugumut, Cumberland Sound	1858	IX (ca.)	Late	1			Barron, 1895:101.
290	Above Nugumut, Cumberland Sound	1858	X	1		1 killed	19½ tons of oil and nearly 1 ton of baleen.	Barron, 1895:105-107; Warmow, 1859:88.
291	Cumberland Sound	1858	X	3-9 (ca.)	Many			Barron, 1895:107.
292	Off Hall Peninsula near Frobisher Bay	1858	X	1st week (ca.)	Many			"
293	Vicinity of Elwin Bay, W side of Prince Regent Inlet	1859	VIII	17	1			M'Clintock, 1863:144.
294	Off mouth of Pond Inlet	1849	VII	10-20		3 killed, 1-2 pursued		Goodsir, 1850:89-92.
295	Pond Inlet	1849	VII	17		1 killed, large female	In a crack in the ice.	Goodsir, 1850:94-98.
296	E side of one of the Wollaston Islands, 2 mi SW of NW tip of Bylot Island, on the shore of a cove	1849	VIII	Early		ca. 1	Remains of Eskimo summer house was found from "some seasons back"; "a few little bits of baleen" surrounded the house.	Goodsir, 1850:111.
297	Off Home Bay, NE Baffin Island coast	1849	IX (ca.)			1 killed, medium size		Goodsir, 1850:116.
298	Just S of Home Bay, NE Baffin Island	1849	IX (ca.)		"Numerous" "dozens"	1 killed, large	*Advice* came upon a "run" of whales.	Goodsir, 1850:116-117.
299	Just S of Home Bay, NE coast of Baffin Island	1849	IX (ca.)		"Dozens"	3-4 killed	Around a small ice-floe.	Goodsir, 1850:117.
300	Just S of Home Bay, N of Cape Searle, NE coast of Baffin Island	1849	IX (ca.)			1 killed, large		Goodsir, 1850:117-118.
301	Just S of Home Bay, N of Cape Searle, NE coast of Baffin Island	1849	IX (ca.)			1 large	Carcass found. "It had been mortally wounded by ... ships, far to the northward, and swam thus far ere it died ... It had just floated to the surface when it was first seen." It was large, with good baleen.	Goodsir, 1850:120-126.
302	Exeter Bay, SE coast of Baffin Island	1849	IX (ca.)			1 large	A "krang" (whale carcass stripped of blubber and baleen) of a large whale was found. The whale had been killed a few days before by a ship.	Goodsir, 1850:143.
303	Cape [Henry] Kater, off the land floe, SE tip Henry Kater Peninsula, NE coast of Baffin Island [Cape Raper, (Markham, 1874)]	1860	VI (ca.)			1 killed		Barron, 1895:123.
304	Between Scott Inlet and Cape Kater, NE coast of Baffin Island	1861	VII (ca.)		A number	1 killed		Barron, 1895:138.
305	Off Home Bay, NE coast of Baffin Island	1861	IX		Many		*Truelove* could not get near them due to bay ice.	Barron, 1895:140.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
306	Off Home Bay, NE coast of Baffin Island	1861	IX	Late in month (ca.)	Several			Barron, 1895:140.
307	Pond Inlet, off the land floe	1862	VI (ca.)			1 killed		Barron, 1895:151.
308	Pond Inlet, off the land floe	1862	VI (ca.)			13 killed		"
309	Off Pond Inlet, at the land floe	1862	VI (ca.)			9-12 killed	By 8 steam whalers made fast to the land floe off Pond Inlet.	"
310	Pond Inlet, off the land floe	1862	VI (ca.)			1 killed		"
311	Between Pond Inlet and Home Bay, NE coast of Baffin Island	1862	Late VI to early VII (ca.)		Many		By *Polynia*.	Barron, 1970:152.
312	64°56′N 66°W, S side of Cumberland Sound	1862	IX	26	1			Lubbock, 1937:458.
313	64°56′N 66°W, S side of Cumberland Sound	1862	IX	27	2			"
314	64°56′N 66°W, S side of Cumberland Sound	1862	IX	29	A number			Lubbock, 1937:459.
315	64°56′N 66°W, S side of Cumberland Sound	1862	IX	30	Several	1 killed		"
316	Home Bay, NE coast of Baffin Island	1862	IX	Late in month (ca.)	Many			Barron, 1895:157.
317	65°10′N 67°10′W, S side of Cumberland Sound	1862	X	6	Several			Lubbock, 1937:459.
318	65°10′N 67°10′W, S side of Cumberland Sound	1862	X	7	Many			Lubbock, 1937:459.
319	65°10′N 67°10′W, S side of Cumberland Sound	1862	X	8	Numerous			"
320	65°10′N 67°10′W, S side of Cumberland Sound	1862	X	9		1 killed, very large		Lubbock, 1937:378,459.
321	65°10′N 67°10′W, S side of Cumberland Sound	1862	X	11	2			Lubbock, 1937:459.
322	65°10′N 67°10′W, S side of Cumberland Sound	1862	X	12	1			Lubbock, 1937:459.
323	65°10′N 67°10′W, S side of Cumberland Sound	1862	X	13	Several			"
324	Cumberland Sound	1862	Late in season			3 killed	By the *Active*; 2 of these probably the same as 2 *Active* captures previously listed, 30 IX 1862 and 9 X 1862.	Lubbock, 1937:378.
325	In Niatlik [Niante?], Cumberland Sound	1863	VII (ca.)		Many			Barron, 1895:163.
326	Off Niatlik [Niante?], Cumberland Sound	1863	VII		A number			Barron, 1895:163.
327	Off Niatlik [Niante?], Cumberland Sound	1863	VII (ca.)			1 killed		Barron, 1895:161.
328	Off Niatlik [Niante?], Cumberland Sound *or* Niantilik [Niante Harbour?], SE coast of Cumberland Sound	1863	ca. IX 3 days [late in 1863 season]			5 killed, large		Barron, 1895:163; Lubbock, 1937:382.
329	"Southern fishery", between 72° and 73°N, 100 mi (est.) offshore	1863				1 killed, large		Lubbock, 1937:381.
330	"Southern fishery", between 72° and 73°N, 100 mi (est.) offshore	1863				7 killed, large	130 tons (est.) of oil.	"
331	"Southern fishery", between 72° and 73°N, 100 mi (est.) offshore	1863				1 killed, large	30 tons of oil.	"
332	150 mi up Roes Welcome Sound	1863	[probably VIII]			3 killed		"
333	Between Marble Island and Cape Fullerton, Hudson Bay	1863	[probably VIII]		"Full of whales"			Chapel *in* Lubbock, 1937:381.
334	Roes Welcome Sound	1863	[probably VIII]		"Legions of whales"			"
335	Exeter Sound, SE coast of Baffin Island	1865	VIII (ca.)		"Numbers"		"Plentiful, but moving rapidly across the bay."	Barron, 1895:190-191.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
336	Exeter Sound, SE coast of Baffin Island	1865	VIII (ca.)			1 killed		Barron, 1895:191.
337	Exeter Sound, SE coast of Baffin Island	1865	VIII (ca.)			2 killed		Barron, 1895:192.
338	Exeter Sound, SE coast of Baffin Island	1865	IX (ca.)		"Plentiful"		The ice in the sound often prevented whalers from getting near whales.	Barron, 1895:195.
339	Repulse Bay	1865	VIII	15-16		8 killed		Low, 1906:277; Nourse, 1879:190.
340	Off Pond Inlet	1866	VI	14	1			Smith, 1922:33.
341	Off Pond Inlet	1866	VI	14-30	Several	Attempted hunting		Smith, 1922:34.
342	Off Pond Inlet	1866	VI	30	1			"
343	Off Pond Inlet	1866	VI	30	1			Smith, 1922:35.
344	Off Pond Inlet	1866	VI	30		1 killed	Possibly same as one sighted earlier in day.	Smith, 1922:34-35.
345	Off Pond Inlet	1866	VI	30		1 killed	Possibly same as one earlier in day.	Smith, 1922:35.
346	Off Pond Inlet	1866	VII	31	3		*Diana* lowered her boats, but could not approach the whales due to the great quantity of loose ice, extending to the horizon.	Smith, 1922:41.
347	Off Pond Inlet, off the land floe	1866	VII	31	3			Smith, 1922:41-42.
348	Navy Board Inlet [close to shore, probably at mouth]	1865	VIII	10	1 large		Close to shore, moving west rapidly.	Philphots, 1869:372.
349	Off Pond Inlet	1866	VIII	1st 2 weeks	A few		In leads among the "ice-fields."	Smith, 1922:42.
350	Off Pond Inlet	1866	IX	3		1	Carcass seen in the ice.	Smith, 1922:56.
351	In middle of Baffin Bay, 150 mi from Scott Inlet, NE coast of Baffin Island	1866	IX	13	1			Smith, 1922:70.
352	Coast of Repulse Bay	1866	Summer			1 killed		Hall, 1876:196.
353	Off Button Islands, mouth of Hudson Strait	1867	III	8	1			Smith, 1922:220.
354	Prince Regent Inlet	1868				40 killed, mostly small		Lubbock, 1937:393.
355	Admiralty Inlet	1869			"Abounds in whales"		Remains ice-free in summer.	Hall, 1876:207.
356	Admiralty Inlet	1869				5 large, killed	By natives.	Hall, 1876.
357	12 mi (est.) N of Cape Hay, Bylot Island, in the open of Lancaster Sound	1871	VI	24	"Numbers"			Lubbock, 1937:399.
358	12 mi N of Cape Hay, Bylot Island, in Lancaster Sound	1871	VI	25		1 killed		"
359	12 mi (est.) N of Cape Hay, Bylot Island, in Lancaster Sound	1871	VI	26	Some			Lubbock, 1937:399.
360	Off Possession Bay, northern coast of Bylot Island	1871	VII	2	"Numbers"			"
361	In Pond Inlet, at edge of the land floe	1871	VII	6	A few		Among ice floes.	"
362	[Probably] in Pond Inlet	1871	VII	10	A few		A few whales and "great numbers" of narwhals were seen around the ship.	"
363	Admiralty Inlet, in the open water, near the land floe	1871	VII	23	"Great numbers"			"
364	Admiralty Inlet	1871	VII	27	"Great numbers"		Ice was heavy.	"
365	Near mouth of Admiralty Inlet	1871	VII	31	Many			Lubbock, 1937:400.
366	Near 61°N 63°W, off Resolution Island, mouth of Hudson Strait	1873	V	15	Some		First sighting of the season on the "southwest" ground.	Markham, 1874:37-38.
367	Near 61°N 63°W, off Resolution Island, mouth of Hudson Strait	1873	V	16	1			Markham, 1874:39.
368	Near 61°N 63°W, off Resolution Island, mouth of Hudson Strait	1873	V	16-20	Many			Markham, 1874:44.
369	Near 61°N 63°W, off Resolution Island, mouth of Hudson Strait	1873	V	20		1 killed		Markham, 1874:44.
370	Near 61°N 63°W, off Resolution Island, mouth of Hudson Strait	1873	V	21-22	Some			Markham, 1874:47.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
371	Near 61°N 63°W, NE of Resolution Island, mouth of Hudson Strait	1873	V	23		1 killed, 40-50 ft, male		Markham, 1874:50-57; Lubbock, 1937:403.
372	Off mouth of Lancaster Sound	1873	VI	Early in month	A number, mostly small			Markham, 1874:133.
373	Off mouth of Lancaster Sound	1873	VI	13		1 killed	The first captured by the Dundee fleet since leaving the "southwest fishing".	Markham, 1874:126.
374	Off mouth of Lancaster Sound	1873	VI	15	Some			Markham, 1874:131.
375	Off mouth of Lancaster Sound, off Cape Byam Martin, E coast of Bylot Island	1873	VI	15		4 killed, 2 males, 2 females		Markham, 1874:131; Lubbock, 1937:403.
376	Off mouth of Lancaster Sound	1873	VI	16		1 killed		Markham, 1874:135-136.
377	10 mi off entrance to Lancaster Sound	1873	VI	17	Some			Markham, 1874:136.
378	Off Cape Walter Bathurst, E coast of Bylot Island, off mouth of Lancaster Sound	1873	VI	19		1 killed		Markham, 1874:141-144; Lubbock, 1937:403.
379	Off entrance to Lancaster Sound	1873	VI	23	Several			Markham, 1874:150.
380	Off Cape Walter Bathurst, E coast of Bylot Island, off mouth of Lancaster Sound	1873	VI	23		2 killed, 1 male, 1 female		Markham, 1874:150-151; Lubbock, 1937:403.
381	Off Cape Bowen, NE coast of Baffin Island	1873	VI	24		1 killed, female	10 ft 4 in. baleen.	Markham, 1874:153; Lubbock, 1937:403.
382	Off mouth of Lancaster Sound	1873	VI	25	Some			Markham, 1874:152.
383	Off mouth of Lancaster Sound	1873	VI	25	Several			"
384	Off Cape Bowen, NE coast of Baffin Island	1873	VI	25		1 killed, male		Markham, 1874:154-156; Lubbock, 1937:403.
385	Off Prince Regent Inlet	1873	VI	28		1 killed, female		Lubbock, 1937:403.
386	5 mi (est.) off mouth of Prince Regent Inlet, in Lancaster Sound	1873	VI	30	Some, small			Markham, 1874:167.
387	Off mouth of Prince Regent Inlet, in Lancaster Sound	1873	VI	30		1 killed, small		Markham, 1874:167; Lubbock, 1937:403.
388	Off Batty Bay, W side of Prince Regent Inlet	1873	VI	30	Some			Markham, 1874:167.
389	Off mouth of Prince Regent Inlet, in Lancaster Sound	1873	VI	30		3 killed, 1 female, 2 males		Markham, 1874:168-171; Lubbock, 1937:403.
390	Off Port Leopold, S side Barrow Strait [sighting]; off Cape Hurd, SW Devon Island [capture]	1873	VI	30	2, female and calf	1 killed, female		Markham, 1874; 168-171; Lubbock, 1937:403.
391	Off mouth of Prince Regent Inlet, in Lancaster Sound	1873	VII	1	Some		The ship struck one whale with "its fore foot".	Markham, 1874:172.
392	Off mouth of Prince Regent Inlet, in Lancaster Sound	1873	VII	4	Several			Markham, 1874:188.
393	In Barrow Strait, off mouth of Prince Regent Inlet	1873	VII	5	5; 2 large, 2 small, 1 calf	4 killed, 2 females, 2 males		Lubbock, 1937:403.
394	Off mouth of Prince Regent Inlet, in Lancaster Sound	1873	VII	6	Some			Markham, 1874:191.
395	Off Point Sargent, SW Lancaster Sound	1873	VII	6		1 killed, female		Markham, 1874:191; Lubbock, 1937:403.
396	Off the "Middle Ice" of Baffin Bay, [off mouth of Lancaster Sound, between Cape Byam Martin and Cape Graham Moore]	1873	VII	9		1 killed, large male		Markham, 1874:293; Lubbock, 1937:403.
397	Off Cape Graham Moore, SE tip of Bylot Island	1873	VII	10	1	1 killed, large male		Markham, 1874:211-212; Lubbock, 1937:403.
398	Off Cape Graham Moore, SE tip of Bylot Island	1873	VI	13		1 killed, large male		Lubbock, 1937:403.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
399	Off Navy Board Inlet, in Lancaster Sound	1873	VII	19	1			Markham, 1874:223.
400	Off mouth of Admiralty Inlet, in Lancaster Sound	1873	VII	20	1			Markham, 1874:223-224.
401	In Admiralty Inlet	1873	VII	20		1 killed, small male		Lubbock, 1937:403.
402	In Admiralty Inlet	1873	VII	22	2			Markham, 1874:228.
403	Off Neill's Harbour [Port Neill?], E side of Prince Regent Inlet	1873	VII	29	Some	1 killed, large female		Markham, 1874:234-235.
404	Mouth of Prince Regent Inlet	1873	between 7 VII and 10 VIII		Pod of 50			Van Beneden, 1887:41.
405	Near Cape Garry, W side of Prince Regent Inlet	1873	between 7 VII and 10 VIII		3			"
406	Near Fury Beach, W side of Prince Regent	1873	between 7 VII and 10 VIII		Many			"
408	Off Batty Bay, W side of Prince Regent Inlet	1873	VIII	1	Some	1 killed, small male		Markham, 1874:239; Lubbock, 1937:403.
409	In Creswell Bay, W side of Prince Regent Inlet	1873	VIII	2	Some			Markham, 1874:241.
410	Off Cape Garry, W side of Prince Regent Inlet	1873	VIII	9	Some		Moving south.	Markham, 1874:260-261.
411	Off Cape Garry, W side of Prince Regent Inlet	1873	VIII	9		1 killed, male	Moving south.	Markham, 1874:260-261; Lubbock, 1937:403.
412	Off Cape Garry, W side of Prince Regent Inlet	1873	VIII	11		1 killed, large female	Last whale taken by *Arctic* in 1873 season; moving south.	Markham, 1874:268; Lubbock, 1937;403.
413	Off Cape [Henry] Kater, NE coast of Baffin Island	1873	VIII	20	Several			Markham, 1874:279.
414	70 miles off Cape Hewett, NE coast of Baffin Island	1873	VIII	27	Several			Markham, 1874:283.
415	Annanatook, Cumberland Sound	1877	X	24	1			Howgate, 1879:35.
416	Off Cape Kendall, Southampton Island	1878	VII	2 (ca.)		4 killed		Wakeham, 1898:59.
417	Off Fisher Strait, northern Hudson Bay	1878	VII	26		1 killed	43 bbl of oil.	Ferguson, 1938:24,26,34.
418	Off Cape Fullerton, W side of Roes Welcome Sound	1878	VIII	1		1 killed	83 bbl of oil.	Ferguson, 1938:35.
419	Off Whale Point, W side of Roes Welcome Sound	1878	VIII	24		1 killed, large	Blubber 18 in. thick in places. Oil yield was 130 bbl; the baleen weighed 2900 lb. Said to have been 95 ft long [sic].	Ferguson, 1938:41,42.
420	Off Depot Island, Hudson Bay	1878	VIII	16		1 killed, small		Ferguson, 1938:39.
421	Off Whale Point, W side of Roes Welcome Sound	1878	IX	5		1 killed	84 bbl of oil.	Ferguson, 1938:43.
422	Near New Gummiute, near Monument Island, head of Frobisher Bay	1878	Autumn			1 killed, large		Wakeham, 1898:59.
423	Off Depot Island, Hudson Bay	1879	V	29	1			Ferguson, 1938:150.
424	Off Depot Island, Hudson Bay	1879	V	31	1			Ferguson, 1938:151.
425	Off Depot Island, Hudson Bay	1879	V	31	1			"
426	Off Depot Island, Hudson Bay	1879	V	31	Some			"
427	Off Depot Island, Hudson Bay	1879	VI	3	Several			Ferguson, 1938:151,152.
428	Off Depot Island, Hudson Bay	1879	VI	3		1 killed	Lost in an ice jam and recovered the next day.	Ferguson, 1938:152.
429	Off Depot Island, Hudson Bay	1879	VI	4		1 killed	This whale and the one killed the previous day, and recovered on this date produced 145 bbl of oil.	"
430	Off Cape Fullerton, W side of Roes Welcome Sound	1879	VI	12	A number			Ferguson, 1938:153.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
431	Off Cape Fullerton, W side of Roes Welcome Sound	1879	VI	13	A number			Ferguson, 1938:153.
432	Off Cape Fullerton, W side of Roes Welcome Sound	1879	VI	14	1			"
433	Off Cape Fullerton, W side of Roes Welcome Sound	1879	VI	15	A number	1 killed		"
434	NE of Marble Island, Hudson Bay	1879	VI	15		1 killed	57 bbl of oil.	Ferguson, 1938:155.
435	Off W shore of Southampton Island, northern Hudson Bay	1879	VI	29	A number			Ferguson, 1938:159.
436	Off W shore of Southampton Island, northern Hudson Bay	1879	VI	30		1 killed	65 bbl of oil.	Ferguson, 1938:154.
437	Off W shore of Southampton Island, northern Hudson Bay	1879	VI	30		several killed (3+)	At least one whale killed per ship.	Ferguson, 1938:159.
438	Off W shore of Southampton Island, northern Hudson Bay	1879	VII	2	A number			Ferguson, 1938:160.
439	Off W shore of Southampton Island, northern Hudson Bay	1879	VII	3	A number			"
440	Off Whale Point, W side of Roes Welcome Sound	1879	VII	4-9	A number			"
441	Off Whale Point, W side of Roes Welcome Sound	1879	VII	14		1 killed	87 bbl of oil.	Ferguson, 1938:162,163.
442	Off Whale Point, W side of Roes Welcome Sound	1879	VII	16	A number			Ferguson, 1938:163.
443	Off Cape Kendall, SE Roes Welcome Sound	1879	VII	29		1 killed	95 bbl of oil.	Ferguson, 1938:168,169.
444	Port Burwell Harbour, Killinek Island, mouth of Hudson Strait	1884	VIII	15	"A number"		No ice yet in sight. Identification not definite.	Gordon, 1886:43.
445	Port Burwell harbour, Killinek Island, mouth of Hudson Strait	1884	IX	1	"Numerous"		Some small icebergs in Hudson Strait.	Gordon, 1886:43.
446	Skynner's Cove [Nachvak Bay], NE coast of Labrador	1884	X	16	1		No ice in the bay, but some icebergs in Davis Strait.	Gordon, 1886:45.
447	Cumberland Sound	1885				2 killed		Lubbock, 1937:417.
448	Prince of Wales Sound, Hudson Strait, southern coast	Between VIII 1885 and IX 1886			2			Gordon, 1887:75.
449	Prince of Wales Sound, Hudson Strait, southern coast	Between VIII 1885 and IX 1886				3	Pieces of skeletons found on the shore.	"
450	Port Laperiere [Cape Digges], outer Digges Island, SW end of Hudson Strait	1886	V	7	1 large		Heavy ice, with narrow, shifting leads of open water.	Gordon, 1887:54.
452	Barrow Strait	1886	VII	5		2 killed, juveniles, male and female	7 tons of oil together.	Van Beneden, 1887:24.
453	Near 61°40'N 67°30'W, north-central Hudson Strait	1886	VII	10	1		First bowhead of the season to be sighted. The northern part of the Strait was open water, while heavy ice was packed along the south shore of Hudson Strait.	Gordon, 1887:6.
454	Prince Regent Inlet	1888				3 killed, "smallish"		Lubbock, 1937:420.
455	Lancaster Sound	1888			13	8 killed	Only 13 whales were seen in Lancaster Sound in 1888, of which 8 were killed, including 3 in Prince Regent Inlet, described in previous entry.	"
456	At "Middle Ice", Baffin Bay [off the mouth of Lancaster Sound, between Cape Byam Martin and Cape Graham Moore]	1890	Mid-VI			1 killed, large		"
457	Prince Regent Inlet	1890	After VI		"Plenty"		In heavy pack ice.	Lubbock, 1937:422.
458	Prince Regent Inlet	1890				4 killed		"

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
459	Off Cape Eglinton, NE coast of Baffin Island	1890				1 killed		Lubbock, 1937:422.
460	Off Cape Kater, NE coast of Baffin Island	1890				1 killed		"
461	Along coast of Baffin Island	1890				5 killed, large	Including the 2 whales described in the previous two entries.	"
462	Off Baffin Island coast	1890			Many		"On the move," were difficult to approach.	"
463	Off Cape Eglinton, NE coast of Baffin Island	1892	XI	6	Large pod		Moving south.	Lubbock, 1937:425.
464	Off Cape Kater, NE coast of Baffin Island	1892	XI	9	Large pod		Believed to be same group as seen 3 days earlier off Cape Eglinton, 100 miles (est.) to the north. Moving southward, pursued by *Nova Zembla.*	"
465	Cumberland Sound, whaling station	1892				1 killed		"
466	Lancaster Sound	1893	End VI to mid-VII			10 killed, 1 escaped	By *Aurora,* including 4 females and 3 calves. One other calf escaped.	Lubbock, 1937:427.
467	Lancaster Sound	1893	End VI to mid-VII			1 killed, calf	Apparently the same as the one which escaped capture by the *Aurora,* described above.	Lubbock, 1937:427-429.
468	Near Coutts Inlet, NE coast of Baffin Island	1893	Mid-IX			4 killed		"
469	Coutts Inlet, NE coast of Baffin Island	1893	IX	27		2 killed		"
470	[probably] near Coutts Inlet, NE coast of Baffin Island	1893	X	8		1 killed		"
471	"West water", [probably Pond Inlet or Lancaster Sound]	1894				6 killed, "fair" size		"
472	Off Martin's Mountains, the southern point of Lancaster Sound	1894				1 killed, large	12 ft baleen.	"
473	Cumberland Sound whaling stations	1895				3 killed	20 tons of oil.	Lubbock, 1937:431.
474	Off Coutts Inlet, NE coast of Baffin Island	1895				2 killed		"
475	Off Coutts Inlet, NE coast of Baffin Island	1895				1 killed		"
476	Off Cape Kater, NE coast of Baffin Island	1897				1 killed		Lubbock, 1937:434.
479	Off Coutts Inlet, NE coast of Baffin Island	1899	[probably late in season]			2 killed		Southwell, 1900:70; Lubbock, 1937:437.
480	Eclipse Sound	1899				3 killed, small		"
481	Lancaster Sound	1899	Early VII			2 killed, female + calf		Southwell, 1900:69.
482	In Pond Inlet	1899				1 killed, very small	4 ft baleen.	"
483	In Pond Inlet	1899				1 killed		"
484	In Eclipse Sound	1899			"Considerable number"			Southwell, 1900:70.
486	In Lancaster Sound	1899				2 killed, small		Southwell, 1900:69.
487	Mostly in Lancaster Sound and Coutts Inlet, NE Baffin Island	1899				10 killed	*Diana* killed 10 whales, probably including the 2 above whales (see entry 486).	Southwell, 1900:70.
488	Off Coutts Inlet, NE coast of Baffin Island	1899				2 killed, large	*Balaena.*	"
489	Cumberland Sound whaling stations	1899				2 killed		Lubbock, 1937:437.
490	Coutts Inlet, NE coast of Baffin Island	1900				1 struck/lost		Lubbock, 1937:439.
491	Coutts Inlet, NE coast of Baffin Island	1900				1 struck/lost, large		Lubbock, 1937:438-439.
492	Cumberland Sound whaling station	1900				1 killed	10 cwt of baleen.	Lubbock, 1937:439.
493	Pond Inlet	1900				3 killed, small		"
494	Coutts Inlet, NE coast of Baffin Island	1900				2 killed, large	12 ft baleen.	"
495	Hudson Strait	1900				1 killed, small		"
496	At whaling station on Fisher Strait, southern coast of Southampton Island, northern Hudson Bay, several miles north of Cape Low on Bay of Gods Mercy	1899-1901				3 killed		"

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
497	Southampton Island	1901	IX			2 killed		Lubbock, 1937:440.
498	Cumberland Sound, whaling stations	1901				2 killed		Lubbock, 1937:441.
499	Hudson Strait	1902				1 killed, small	9 cwt of baleen. Ice was very thick.	Lubbock, 1937:442.
500	Hudson Strait	1902			Numerous		In thick ice.	"
501	Cape Haven whaling station, (62°54′N 64°37′W) between Frobisher Bay and Cumberland Sound, SE Baffin Island coast	1900-1903				A few killed		Low, 1906:12.
502	Cumberland Sound, whaling stations	1903				2 killed		Low, 1906:10-11.
503	[Probably] off Kekerten Island, Cumberland Sound, NE shore	1903				1 killed		Lubbock, 1937:444-445.
504	Off Kekerten Island, NE Cumberland Sound	1903				4 killed	2 by the *Ernest William.*	Lubbock, 1937:444.
505	Off Mansfield and more southern islands of east side of Hudson Bay	1903 (ca.)	Winter		Some			Low, 1906:257.
506	Off Whale Point, west side of Roes Welcome Sound, southern end	1903			"Plentiful"			Low, 1906:32.
507	Roes Welcome Sound	1904	Winter			1 killed	8 ft 9 in. baleen.	Lubbock, 1937:446.
508	Southern Roes Welcome Sound, between Cape Kendall and Cape Fullerton (63°58′N 88°47′W)	1904	Late VI		1 large			Low, 1906:34.
509	[Probably] eastern end of Pond Inlet	1904	Early summer			2 killed, small		Low, 1906:57.
510	Southampton Island, northern Hudson Bay	1904	To VII	20		1 killed, small		Low, 1906:272.
511	[Probably] Roes Welcome Sound or Repulse Bay	1904	VIII	14		1 killed	9 ft 3 in. baleen.	Lubbock, 1937:446.
512	Mouth of Pond Inlet, at Pond Inlet whaling station	1904	To VIII	23		2 killed, small	500 lb of baleen	Low, 1906:272.
513	Repulse Bay, at whaling station	1904				1 killed, small	500 lb of baleen.	Low, 1906:68,272.
514	North shore of Hudson Strait	1904				1 killed, large	3000 lb of baleen.	Low, 1906:272.
515	Northwestern Hudson Bay	1904			Several			Bernier, 1910:313.
516	Hudson Strait	1904			Several			"
517	Cumberland Sound	1904			A few		Much broken ice was tightly jammed into the sound all summer, preventing whaleboats from reaching open water to hunt.	Low, 1906:62.
518	Pond Inlet, [probably] at mouth in inlet	1908				1 killed		Lubbock, 1937:449.
519	Off mouth of Navy Board Inlet, in Lancaster Sound	1909	VIII	31	1			Bernier, 1910:477.
520	Kekerten Island, NE shore of Cumberland Sound	1909				1 killed, small	3 ft baleen.	Bernier, 1910:424.
521	Whaling stations in Hudson Strait, Cumberland Sound and Pond Inlet	1909				15 killed		Lubbock, 1937:450.
522	Jones Sound	1910	Within 4 days			7 killed, large		"
523	Whaling stations in Hudson Strait, Cumberland Sound and Pond Inlet	1910				18 killed		"
524	Hudson Strait, S side, ca. 9 leagues WNW of Charles Island, at or near 62°50′N	1814	VIII	11		1 attempted kill	In "a vacancy between the ice". First whale seen this voyage.	Chappell, 1817:131.
525	Off mouth of Cumberland Sound, 30 mi SW of 63°59′29″N 61°42′58″W, SSE of Cape Mercy, SE coast Baffin Island	1819	VI	27	1 large		It "raised its head to take breath near the ships" and went "down tail foremost between two pieces of ice" since it "could not turn over to go down in the usual way, head first."	Parry, 1821:9: Anon., 1821:15.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
526	Off SE entrance of Lancaster Sound, approx. 50 mi ENE of Possession Bay, Bylot Island. Near 74°01′57″N 74°59′58″W	1819	VII	30	At least some		"The headquarters of the whales." No ice in site. See Entry No. 137.	Parry, 1821:23-24; Anon., 1821:22.
527	75°33′N, 61°22′W	1818	VII	31		a male killed, ca. 46 ft		Ross, 1819:xlvi-xlvii,69-71.
528	Near 73°55′18″N 77°40′W, off Bylot Island, 10 mi N of Cape Liverpool in Lancaster Sound	1819	VIII	1	Several, incl. many young		Some loose and heavy streams of ice. See entry No. 140.	Parry, 1821:29; Anon., 1821:25.
529	Near 74°25′31″N 80°04′30″W. N of Cape Hay and Navy Board Inlet, mid-entrance of Lancaster Sound	1819	VIII	3	"a great number"			Parry, 1821:33.
530	Near 73°33′15″N 88°18′17″W, Prince Regent Inlet, near the beach	1819	VIII	15	1, very large			Parry, 1821:46.
531	Near 73°50′N 88°15′W, mouth of Prince Regent Inlet, due W of Cape York	1819	VIII	18		1 attempted kill		Parry, 1821:47.
532	Between Cape Crauford, W coast Admiralty Inlet, and Cape Fanshawe, Bylot Island, a few mi offshore, off east side of mouth of Navy Board Inlet, in Lancaster Sound	1820	VIII	31	1		Some bergs and land-fast ice along south side of Lancaster Sound.	Parry, 1821:268.
533	Principally near Clyde Inlet, also in area of Agnes Monument, NE Baffin Island coast	1820	IX	5	12+, large			Parry, 1821:276.
534	East of Clyde Inlet, NE Baffin Island coast	1820	IX	5		1 killed	*Friendship* of Hull.	"
535	Between S shore Clyde Inlet and Cape Kater, NE Baffin Island coast, 1 mi or so offshore	1820	IX	9	"Several young"			Parry, 1821:290.
	Between Cape Kater and Cape Hooper, off Home Bay, NE coast of Baffin Island	1820	IX	10		1	Carcass found.	"
536	Merchants Bay, SE coast Baffin Island, near S tip Padloping Island	1820	IX	13	"A great many"		Heavy ice with bergs.	Parry, 1821:292.
537	Just off Merchants Bay, SE coast of Baffin Island	1820	IX	14	"A great many"		Thick ice with bergs.	"
538	Hudson Strait mouth, ca 10 mi ENE of Black Bluff on Resolution Island	1821	VII	1	1 large		In lead; heavy ice with bergs.	Lyon, 1824:7.
539	Entrance of Hudson Strait, just S of Resolution Island	1821	VII	17	1		Heard blowing.	Lyon, 1824:12.
540	Near E entrance of Frozen Strait, in the strait	1821	VIII	12	1		Heavy moving ice was besetting ships.	Lyon, 1824:43.
541	Bay "at bottom" of Repulse Bay	1821	VIII	22	"Numerous"			Lyon, 1824:55.
542	Gore Bay, SE Melville Peninsula, western Foxe Basin	1821	VIII	27	2 large		Heading north.	Parry, 1824:71.
543	Near head of Lyon Inlet, SE Melville Peninsula, SW Foxe Basin	1821	IX	6-15	Several large		Heavy ice starting to fill mouth of Lyon Inlet.	Lyon, 1824:73.
544	Northernmost shore of Gore Bay, SE Melville Peninsula, SW Foxe Basin	1821	IX	19	Several		No ice in the bay.	Parry, 1824:106.
545	In Safety Cove, Lyon Inlet, SE Melville Peninsula	1821	27 IX - 3X		2 large		Much packed and young ice in the inlet.	Lyon, 1824:83.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
546	Near SE point of Winter Island, Foxe Channel, near 66°11′N 83°10′W	1821	X	8 (ca.)		Several attempted kills	Ice prevented boats from reaching the whales.	Parry, 1824:126.
547	In Foxe Channel, SE of SE extremity of Lyon Inlet	1821	XII	1	1			Lyon, 1824:96.
548	In Foxe Channel, S of SE tip of Lyon Inlet	1822	I	22	1			Lyon, 1824.
549	Near Tern Island, Igloolik area, NW Foxe Basin	1822	VIII	4		Several attempted kills		Lyon, 1824:255.
550	Near Tern Island, Igloolik Island area, NW Foxe Basin	1822	VIII	5		1 killed, female, 43 ft 9 in.	Longest baleen 9 ft 1.5 in.	Lyon, 1824:256.Parry, 1824:301.
551	Off eastern entrance of Fury and Hecla Strait, just E of northern tip of Neerlonakto Island	1822	VIII	13	Several		Loose ice drifting away from the floe.	Parry, 1824:307.
552	Off eastern entrance of Fury and Hecla Strait, just N of Neerlonakto Island	1822	VIII	15	1		In space free of ice between 2 islands (2 of the Bouverie Islands). Ice was broken up.	Parry, 1824:308.
553	20 mi N of Winter Island, SW Foxe Basin	1823	VIII	28	1			Lyon, 1824:453.
554	Some mi N of Whale Point, Roes Welcome Sound	1824	IX	9	"A few"		"It is remarkable that this should be the first time of meeting with them."	Lyon, 1825:90.
555	Entrance of Lancaster Sound, mostly along S side, to Prince Regent Inlet (Port Bowen)	1824	Early IX to end IX		20-30, several large and "payable"		Young ice forming rapidly everywhere.	Parry, 1826:36-37.
556	N of Port Bowen, E side of Prince Regent Inlet	1825	VII 1st 2 wks.		"A number"		In the open water to the northward of Port Bowen. This may have been in the mouth of Prince Regent Inlet.	Parry, 1826:89.
557	N of Port Bowen, E side of Prince Regent Inlet	1825	VII	13		1 killed, small	5 ft baleen. In open water. Ice breaking up along coast.	Parry, 1826:89.
558	"Neill's Harbour" (Port Neill), E side Prince Regent Inlet	1825	VIII	27	9-10		"Somewhat below the middle size." Most ice gone, much open water.	Parry, 1826:161.
559	Between Arctic Circle and 58°N, near 58°27′W. Along Greenland coast	1825	17 IX - 24 IX		"A few"			Parry, 1826:168.
560	68°45′N, 60 mi offshore (Greenland or Baffin Island coast)	1827	II	Early		1 killed		Back, 1970 [1836]:489.
561	Between Capes York and Kater, Prince Regent Inlet	1833-1834			"Hundreds"	28 killed		Hall, 1970:131.
562	Along coast of W side of Hudson Bay, near 63°06′14″N, Chesterfield Inlet area	1846	VII	13	"Upwards of a dozen", very large			Rae, 1850:27.
563	Near Cape Fullerton, SW Roes Welcome Sound	1846	VII	15	1 very large		Close to shore, Large pack ice in area.	Rae, 1850:29.
564	Off Whale Point, SW Roes Welcome Sound	1846	VII	19	"A great many"			Rae, 1850:32.
565	60°08′N, near 59°07′W, off mouth of Hudson Strait	1826	V	19	2			Duncan, 1827:4.
566	60°16′N, near 59°07′W, off mouth of Hudson Strait	1826	V	20	1			Duncan, 1827:5.
567	Near 61°N 60°W, off mouth of Hudson Strait, at edge of pack ice in Davis Strait	1826	V	23	1	1 struck/lost		Duncan, 1827:5-6.
568	Near 61°N 60°W, off mouth of Hudson Strait, along edge of Davis Strait pack ice	1826	V	24	2-3	1 killed	11 ft 6 in. baleen.	Duncan, 1827:6-7.
569	Near 61°N 60°W, off mouth of Hudson Strait, along edge of Davis Strait pack ice	1826	V	25	Several			Duncan, 1827:6.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
570	61°43′N 61°W, off mouth of Hudson Strait at pack ice edge	1826	V	26	1			Duncan, 1827:7.
571	Near 61°43′N 61°W, off mouth of Hudson Strait at pack ice edge	1826	V	29	Several			"
572	Near 62°11′N 61°W, off SE Baffin Island	1826	VI	5		1 killed	11 ft 7 in. baleen. Heavy ice.	Duncan, 1827:9.
573	61°50′N. near 61°W, off SE Baffin Island	1826	VI	9	1		"Straggling" ice.	Duncan, 1827:10.
574	Near 68°43′N, near south end Disco Island, Greenland coast, 50 miles from land	1827	II	2		1 killed	9 ft 4 in. baleen. Heavy ice.	Duncan, 1827:85; Lubbock, 1937:266-267.
575	Near 68°43′N, near south end Disco Island, Greenland coast, 50 miles from land	1827	II	1	Several		Heavy ice.	Duncan, 1827:85.
576	Near 68°58′N, Greenland coast, 50 miles from land	1827	II	7	Several			Duncan, 1827:87.
577	Near 68°58′N, Greenland coast, 50 mi from land	1827	II	8	Several			"
578	Greenland coast, at 68°58′N, 50 mi from land	1827	II	15	Several		In heavy ice, with "holes of water."	Duncan, 1827:89.
579	Greenland coast, 68°58′N, 50 mi from land	1827	II	16	Several		Heavy ice.	Duncan, 1827:90.
580	Greenland coast, near 68°58′N, 50 mi from land	1827	II	17	3-4	2 struck,	8 ft 1 in. baleen. At floe edge.	Duncan, 1827:90; Lubbock, 1937:267.
581	Greenland coast, near 68°58′N, 50 mi from land	1827	II	21	Several		Much "bay ice." Vessel was beset in ice.	Duncan, 1827:91.
582	67°34′N, near 62°30′W, off SE Baffin Island coast	1827	III	11	1		In lead of open water among "bay ice."	Duncan, 1827:104.
583	Near 67°25′N 62°30′W, off SE Baffin Island coast	1827	III	13	2		In "bay ice."	Duncan, 1827:105.
584	Near 67°25′N 62°30′W, off Baffin Island E coast	1827	III	14	Several			"
585	Near 67°25′N 62°30′W, off E coast Baffin Island	1827	III	15	1		Heavy ice.	"
586	67°24′N, near 62°30′W, off E coast Baffin Island (?)	1827	III	16	Some			"
587	61°37′N, 61°W, off mouth of Hudson Strait	1827	III	25	1			Duncan, 1827:109.

589	Near 61°37′N 61°W, off mouth of Hudson Strait	1827	III	27	Several			Duncan, 1827:110.
590	67°18′N, in middle Davis Strait	1858	IV	6	2			M'Clintock, 1860:99.
591	In Lancaster Sound and at "ice edge" (Pond Inlet floe edge?)	1858	VIII	Early	"Many"			M'Clintock, 1860:169.
592	Vicinity Prince Leopold Island, E Barrow Strait	1859	VIII	23	1			Sutherland, 1852:v.1:288.
593	Cape Searle area, NE coast Baffin Island	1846	Until mid-or late October		Several			Sutherland, 1852:v.2:325.
594	Pond Inlet floe edge	1845	VI or VII		"Literally swarming"		At the edge of the ice.	Sutherland, 1852:v.2:324-325.
595	N of Whale Point, near 64°56′33″N, Roes Welcome Sound, Southampton Island shore visible	1846	VII	20	Some large		Close-packed ice in area.	Rae, 1850:32.
596	Near Cape Hope, S end of Repulse Bay	1847	VIII	13	1 large			Rae, 1850:179.
597	Near 63°47′33″N, opposite Cape Fullerton, SW Roes Welcome Sound, just offshore	1847	VIII	17	1 large			Rae, 1850:183.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
598	Near 62°13'19"N, near Whale Cove, near S side of Corbett Inlet, NW Hudson Bay	1847	VIII	14	3 large			Rae, 1850:190.
599	Cyrus Field Bay, SE Baffin Island coast	ca. 1855 ("not many years ago" pre-1860)				1 struck		Hall, 1970:217, 1865:247.
600	Cumberland Sound	1857	Spring			1 killed	In open water by floe edge.	Hall, 1970:216.
601	In lower part of Frobisher Bay (or Cyrus Field Bay), SE Baffin Island coast	1860	Late VIII- early IX (est.)			1 killed		Hall, 1970:109.
602	Cyrus Field Bay, SE Baffin Island coast	1860	late IX	(ca. 20-25)		1 killed		Hall, 1970:115.
	Near Clark Harbour on Cornelius Grinnell Bay, SE Baffin Island	1860				1	Bones of whale killed previously.	Hall, 1970:89.
603	In Cyrus Field Bay, SE Baffin Island coast	1861	X	7-10		2 killed		Hall, 1970:411-412.
604	In Cyrus Field Bay, SE Baffin Island coast	1861	X	17		1 killed		Hall, 1970:419.
	On island along coast of Belcher Peninsula, head of Frobisher Bay, SE Baffin Island	1861					Bones of "huge" whale found, portions covered with moss.	Hall, 1970:350.
605	Repulse Bay	1864	VIII		Many, all small	20 killed		Nourse, 1879:65.
606	Whale Point, SE Roes Welcome Sound	1864	IX	1	Some			Nourse, 1879:59.
607	At "Noo-wook" (Nuvuk), between Whale Point and Wager Bay, W Roes Welcome Sound	1864	IX	8-9	Some		Close to shore.	Nourse, 1879:65.
608	Repulse Bay	1865	VII	end	1		Heard blowing.	Nourse, 1879:184.
609	Repulse Bay	1865	VIII	ca. 6	3		Near shore.	Nourse, 1879:186.
610	Repulse Bay	1865	VIII	30	2	1 killed	1500+ lb baleen.	Nourse, 1879:190-192.
611	Repulse Bay	1866	VIII	end	1		First whale of the season. Heard blowing.	Nourse, 1879:283.
612	Repulse Bay	1866	VIII	end		1 killed, large	9 ft 6 in. baleen, 60 bbl oil.	Nourse, 1879:286.
613	Repulse Bay	1867	VIII	late		1 killed		Nourse, 1879:324.
614	Repulse Bay	1868	VIII	31		1 killed	7 ft baleen.	Nourse, 1879:362-364.
615	Repulse Bay	1868	Summer			1 killed		Nourse, 1879:358.
616	Milne Inlet, bottom of Eclipse Sound	1869			Many		Bowheads "abound" here.	Nourse, 1879:370.
617	Lancaster Sound	1884	VII	1	"Good number"			Lindsay, 1911:153.
618	Lancaster Sound, probably Navy Board Inlet area	1884	VII	5		1 killed	10 ft baleen, 13 tons oil.	Lindsay, 1911:157-163.
619	Lancaster Sound, almost opposite mouth of Admiralty Inlet	1884	VII	6		1 attempted kill	Among loose ice.	Lindsay, 1911:163-164.
620	Lancaster Sound, opposite mouth of Admiralty Inlet	1884	VII	8		2 killed	Near ice edge.	Lindsay, 1911:166-168.
621	Lancaster Sound, opposite mouth of Admiralty Inlet, S side of sound	1884	VII	8	Some		"...the fish were coming up the south side [of Lancaster Sound]..."	Lindsay, 1911:168.
622	Lancaster Sound, near mouth of Admiralty Inlet	1884	VII	12		1 attempted kill	In loose ice.	Lindsay, 1911:173.
623	Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VII	17		1 killed		Lindsay, 1911:175.
624	Lancaster Sound, probably area of mouth of Admiralty Inlet	1884	VII	18		1 attempted kill	Among loose ice.	Lindsay, 1911:177.
625	Lancaster Sound, probably near mouth of Admiralty Inlet, S side of sound.	1884	VII	19		1 killed	10½ ft baleen.	Lindsay, 1911:177-178.
626	Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VII	19		1 killed	No ice.	Lindsay, 1911:181-182.
627	Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VII	23			"...the place was swarming with whales, [but] we never got one."	Lindsay, 1911:186.

Table 1 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
628	Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VII	23		1 attempted kill	In loose ice.	Lindsay, 1911:184-185.
629	Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VII	23	1 large		In loose ice.	Lindsay, 1911:185.
630	Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VII	23	2	1 struck/ lost	In loose ice.	Lindsay, 1911:185-186.
631	Lancaster Sound, probably near mouth of of Admiralty Inlet	1884	VII	23		1 attempted kill	In loose ice.	Lindsay, 1911:186.
632	S side of Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VII	24		1 killed		Lindsay, 1911:187.
633	S side of Lancaster Sound, near mouth of Admiralty Inlet	1884	VII	28		1 killed		Lindsay, 1911:188-189.
634	S side of Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VII	31		1 attempted kill		Lindsay, 1911:191.
635	S side of Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VIII	1		1 killed, large		Lindsay, 1911:192.
636	S side of Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VIII	4		1 struck/lost	In loose ice.	Lindsay, 1911:193-194.
637	S side of Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VIII	6		1 attempted kill	Among pans of loose ice.	Lindsay, 1911:194.
638	S side of Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VIII	6		1 attempted kill		Lindsay, 1911:194-195.
639	S side of Lancaster Sound, probably near mouth of Admiralty Inlet	1884	VIII	7	2	1 killed		Lindsay, 1911:195-197.
640	S side of Lancaster Sound, near mouth of Navy Board Inlet	1884	VIII	9		1 killed	Much ice in area.	Lindsay, 1911:198-199.
641	Near entrance of Hudson Strait, between Cape Chidley and Savage Islands	1886	VII	10	1		No ice.	Feilden, 1887:347.
642	Prince of Wales Sound, Hudson Strait	1886-1887				2		Payne, 1888:118.
643	Near 66°44′N 54°30′W, ca. 25 miles off Greenland coast	1910	VII	20	ca. 30		Not much ice.	Bernier, 1911(?):9.
644	At ice edge NE of Cape (Point?) Bathurst, South Bylot Island	1911	VI	28 (ca.)	1 large		Ice heavy around the coast.	Bernier, 1911(?):143.
645	Near Cape Adair, NE Baffin Island coast	1906	X		"Some"			Bernier, 1909:40.
646	Button Point, SW Bylot Island, on Pond Inlet	1907	VII	early	"Not many"			Bernier, 1909:43.

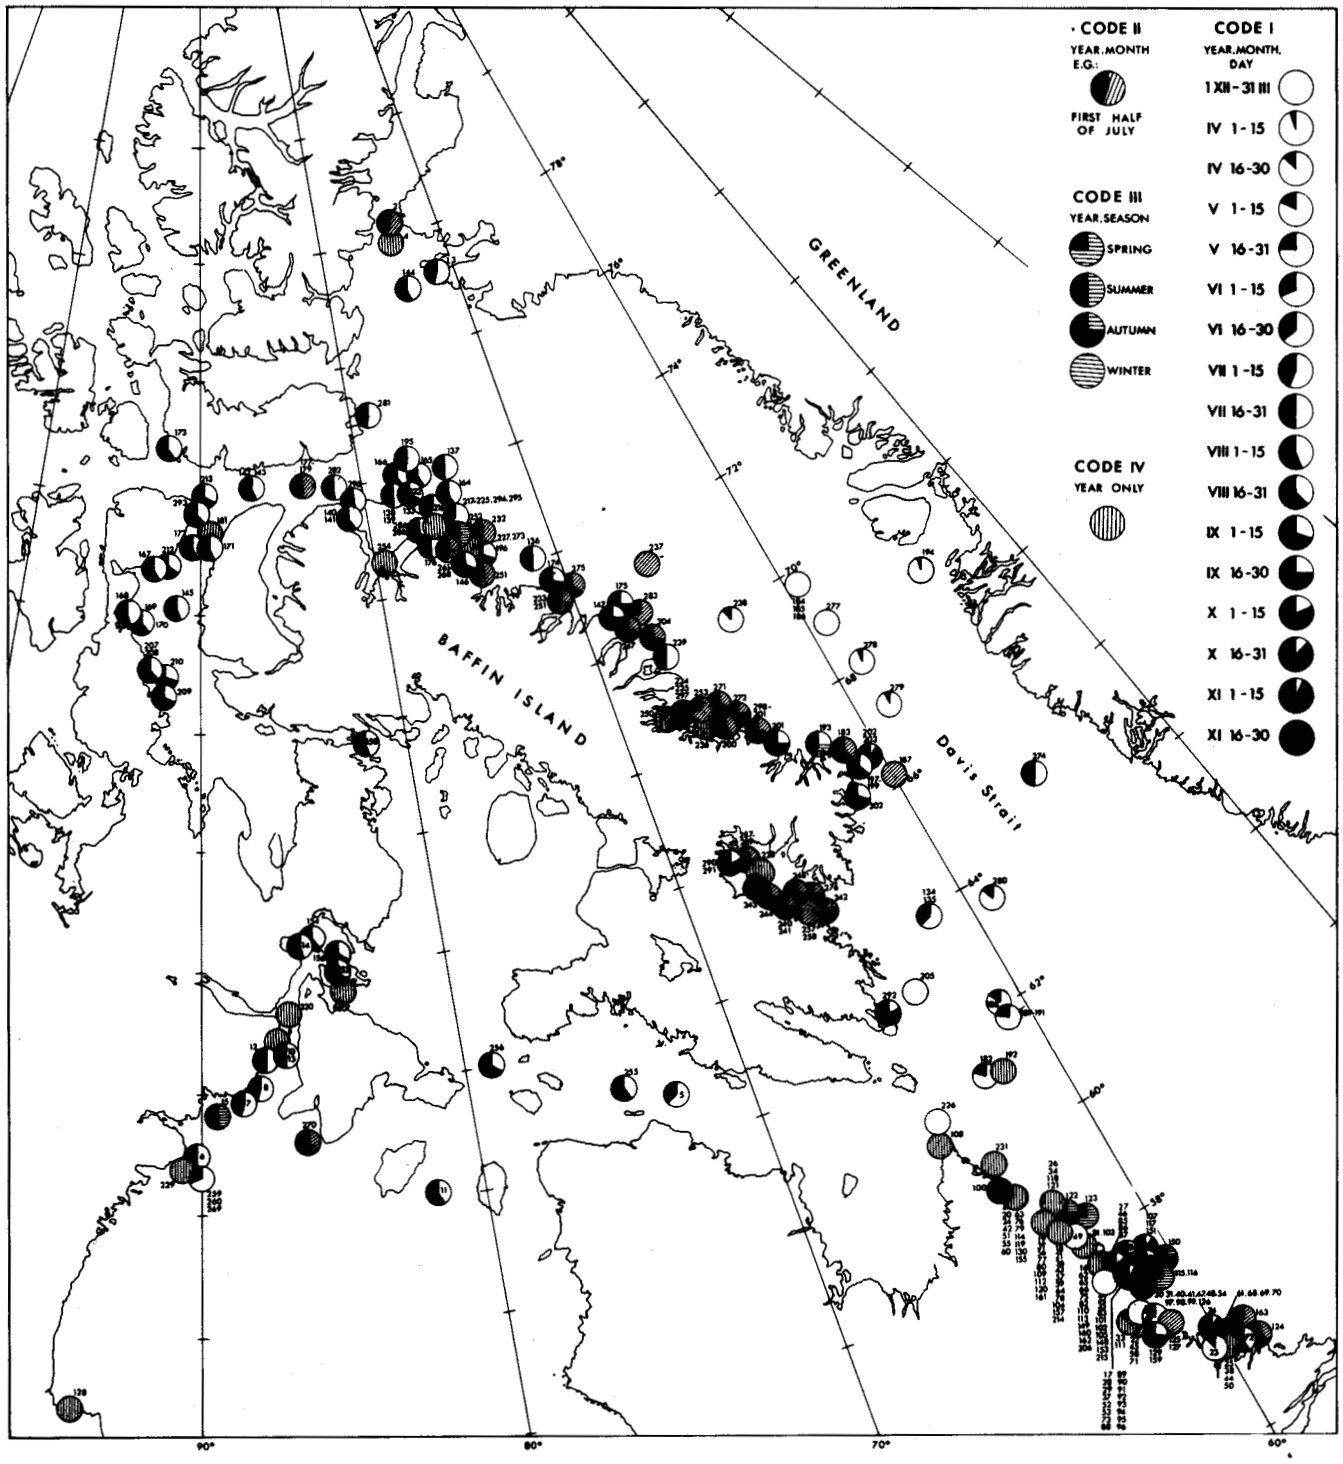

FIG. 1. Bowhead distribution, 1615-1859. Numbers refer to entries on Table 1. Key to plots on this figure applies to Figures 1-4.

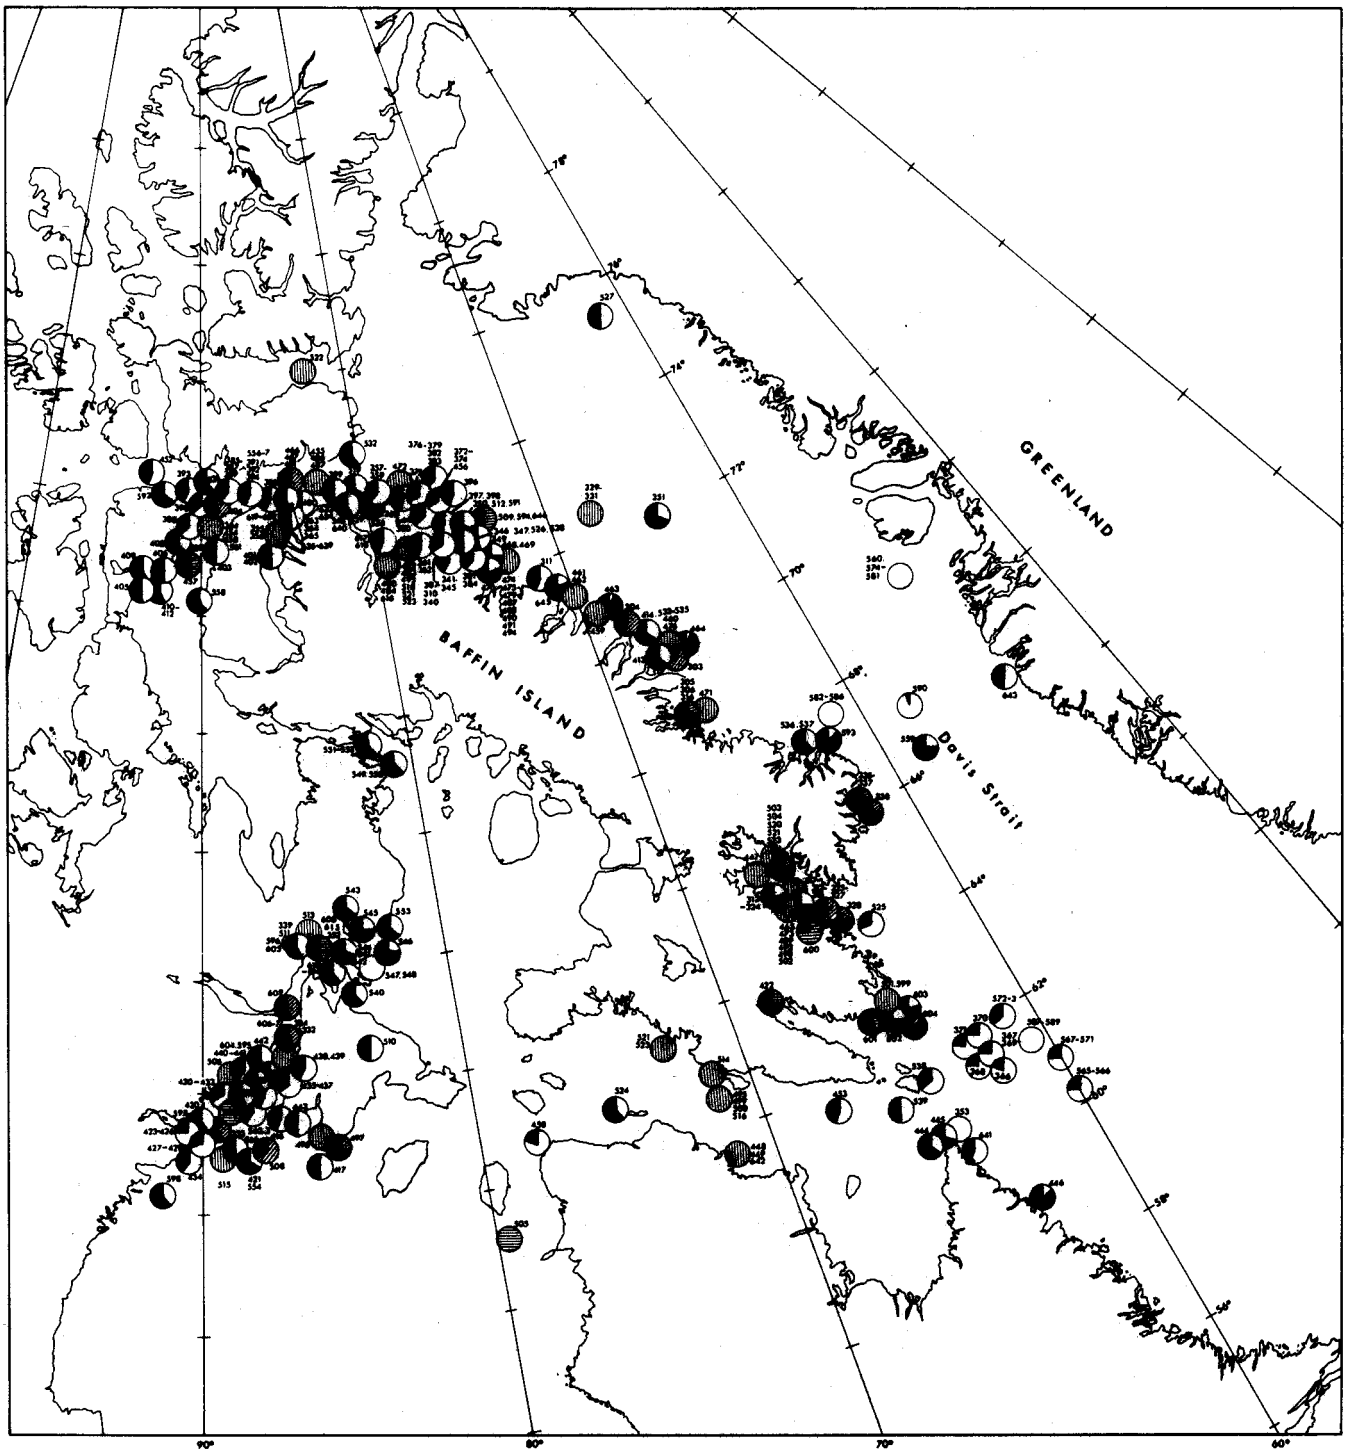

FIG. 2. Bowhead distribution, 1859-1913. Numbers refer to entries on Table 1.

TABLE 2. Occurrences of the bowhead whale in the eastern Arctic, 1919-1939, from Hudson's Bay Company post journals

Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
Coats Island, northern Hudson Bay	1919	VI	23	2 large		"Feeding" in harbour. Whales "quite numerous" here.	HBC Archives, Coats Island Post Journal, B.404/a/1, 1918-1920, Folio 33.
Coats Island, northern Hudson Bay	1919	VII	15		1 attempted kill	Whale observed coming up "through holes in the ice." Struck with 1 harpoon and many spears by Eskimos. Whale escaped with harpoon "in shoulder" and trailing a float, "bleeding badly" while being chased for 2 hours.	HBC Archives, Coats Island Post Journal, B.404/a/1, 1918-1920, Folio 35.
Near Cape Dorset, western end of Hudson Strait	1919	VIII	15		1 attempted kill	A "Right" whale. Attempted kill, harpoon missed.	HBC Archives, B.397/a/2, 1918-1920, Cape Dorset Post Journal, Folio 106.
Coats Island, northern Hudson Bay	1919	VIII	28	1		In the harbour of the HBC Post.	HBC Archives, Coats Island Post Journal, B.404/a/1, 1918-1920, Folio 41.
Coats Island, northern Hudson Bay	1919	IX	27	1		HBC Post harbour.	HBC Archives, Coats Island Post Journal, B.404/a/1, 1918-1920, Folio 46.
Coats Island, northern Hudson Bay	1920	X	1	1 large		Large whale seen moving south. "This is the first seen for the season."	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 11.
Coats Island at "spring quarters" of Inuit	1921	VI	15	2 large		Natives reported seeing 2 large whales at their "spring quarters", the first seen since late the previous fall.	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 59.
Near Beacon Point, Coats Island	1921	VI	23-28	1 large		Appears to have remained in the same area for period 23-28 June.	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 60-61.
Coats Island, northern Hudson Bay	1921	VII	18		1 killed, 30 ft female	Killed with "Dart Piercing Bomb" by natives and HBC Post employees. The whale's tail broke the main boom of the whaleboat. Produced a total of 12,913 lb of blubber and 135 lb of baleen of average length of 2 ft.	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 64.
Southwest coast of Coats Island, northern Hudson Bay	1921	VII	25	1 large			HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 66.
Coats Island, northern Hudson Bay	1921	VIII	4-6	1 large (>30 ft)	attempted kill		HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 69.
Coats Island, northern Hudson Bay	1921	IX	25	1 large			HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 77.
Cumberland Sound, near Pangnirtung post	1921 or 1922	X	8	1 large		"Black whale."	HBC Archives, B.455/a/2, Folio 2, Report upon Sundry Trips and Resources of Country. Cumberland Gulf. 1922.
Coats Island, northern Hudson Bay	1922	IV	24	1			HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 108.
Coats Island, northern Hudson Bay	1922	VI	16	1 large			HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 116.
Coats Island, northern Hudson Bay	1922	VII	1	1 large			HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 119.
Coats Island, northern Hudson Bay	1922	VII	2	2 large	1 struck/lost	Struck with a "Dart Piercing Bomb", but lost. The second whale was chased but not struck.	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 119.
Coats Island, northern Hudson Bay	1922	VII	8	1		Chased, not struck.	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 120.
Coats Island, northern Hudson Bay	1922	VII	29	1 large			HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 123.
Coats Island, northern Hudson Bay	1922	VII	30-31	1		Chased, not struck.	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 123.
Coats Island, northern Hudson Bay	1922	VIII	1-10	1		One whale seen and chased repeatedly.	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 125.
Ca. 40 mi off Cape Pembroke, NE tip of Coats Island	1922	VIII	11		1 large (75 ft long [sic.], baleen of 12 ft) killed	Natives unable to tow whale in, so set it adrift; no part was saved.	HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 127.
Coats Island	1923	X	6	1			HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 174.
Coats Island	1923	X	8-11	1	attempted shot		HBC Archives, Coats Island Post Journal, B.404/a/3, 1920-1927, Folio 174.
Native Point, Southampton Island	1925	VII	22	1			Southampton Island Post Journal, B.404/a/3, Folio 302.
Repulse Bay	1925	15 VIII - 12 IX		1	1 struck/lost	Bowhead, apparently same one, hunted repeatedly for 3 wk; struck but lost on 27 VIII.	HBC Archives, Southampton Island Post Journal, B.404/a/3, Folios 327-330.
Bowdoin Harbour, south of Cape Queen, western Hudson Strait	1929	II	27		1	"Right whale" found frozen in ice; baleen missing; "must have been killed by men last summer."	HBC Archives, Cape Dorset Post Journal, B.397/a/3, 1928-1929, Fo. 21d,23,28.
Repulse Bay, HBC Post	1931	VIII	4	1		"Saw no sign of black whale which has been reported to be in the vicinity."	HBC Archives, Repulse Bay Post Journal, B.472/a/1, 1930-1931, Folio 65.
Clyde River, HBC Post	1932	IX	7	1		"Fairly big" whale seen near post.	HBC Archives, Clyde River Post Journal, B.403/a/3, 1932-1933, Folio 28.

Table 2 (Continued)

Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
Mansel Island, NE Hudson Bay	1930	XI	10		1	"[Fox] signs are quite numerous especially around the Whale ... found last year .... The Whale Meat is presumably in such a putrid state that the dogs will not eat it."	HBC Archives, Mansel Island Post Journal, B.438/a/1, Folio 25.
Clyde River, NE coast of Baffin Island	1934	IX	13	2		Native saw 2 "Greenland whales" out of reach.	HBC Archives, Clyde River Post Journal, B.403/a/4, 1933-1934, Folio 81.
Clyde River, NE coast of Baffin Island	1939	VIII	30	1 large		Large "Greenland whale" seen in the Clyde River HBC Post harbour.	HBC Archives, Clyde River Post Journal, B.403/a/6, 1938-1939, Folio 254.

TABLE 3. Occurrences of the bowhead whale in the eastern Canadian Arctic, 1914-1974

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
1	S. Southampton Island	1924	XI	8	2 very large			Sutton and Hamilton, 1932:90.
1A	Southampton Island	1926	VII	22	1		Soon after breakup in harbour.	"
2	Southampton Island	1926	X	6	5			"
3	Southampton Island	1926	X	23		1 killed		Sutton and Hamilton, 1932:90; Manning, 1944:145; Copland, 1974:44.
4	Southampton Island	1927	VI	21	1 small		Before ice had entirely left the shore.	Sutton and Hamilton, 1932:90.
5	Southampton Island	1928	IX	17		1 killed, large		Sutton and Hamilton, 1932:90; Manning, 1944:145.
6	Southampton Island	1929	VII			1 killed, >45 ft		Sutton and Hamilton, 1932:90.
7	Southampton Island	1929	IX	25	6		One breached repeatedly.	Sutton and Hamilton, 1932:91.
8	Clearwater Fiord, Cumberland Sound	1946	VII			1 killed, 36 ft	First whale killed in this area since 1918.	Anderson, 1947.
9	Chase Island, Frobisher Bay, 63°05'N, 66°55'W	1954	VII	12	2; 1 large, 1 small			RCMP Game Report, July 30, 1954 (Mansfield files).
10	Cape Christian, E. Baffin Island, 70°32'N, 68°18'W	1954	VIII	End	1-2			RCMP Game Report, 1953-54 (Mansfield files).
11	Pangnirtung district, Cumberland Sound	1954			Herds of 5, 7, 8		Numbers of whales seen throughout year in this area, including young. Population thought to be increasing.	RCMP Game Report, 1955 (Mansfield files).
12	SW Hudson Bay	1955	Summer		1 large			Dr. W.J. Felts, Univ. of Minnesota (source uncertain).
13	63°08'N, 89°46'W, S. Roes Welcome Sound	1955	VIII	12	1			Icebreaker *Labrador* (Mansfield files).
14	71°31'N, 68°16'W, Cape Christian area, E. Baffin	1955	IX	20	2		Natives consider sightings becoming more frequent.	RCMP Game Report (Mansfield files).
15	64°03'N, 75°48'W, E of Cape Dorset, Northwest Hudson Strait	1955	XI	5	6; 3 large, 3 small		Close to shore, near tide rip.	Personnel of icebreaker *Labrador* (Mansfield files).
16	Navy Board Inlet, N. Baffin Island	1955	Autumn			1	Carcass found by Eskimos. No other details.	RCMP Game Report 1955-56 (Mansfield files).
17	71°20'N, 84°50'W, Easter Sound, Admiralty Inlet	1955	Autumn			1	Carcass found by Eskimos. No other details.	"
18	Cumberland Sound	1955			Herds of 5-10, est. 50 total		Including many young. An increase in sightings since 1954.	RCMP Game Report 1954-55 (Mansfield files).
19	SW Hudson Bay between Winisk and Churchill	1956	Summer		1 large			Pilot, Transair Ltd.
20	Navy Board Inlet	1956	Summer		A few			RCMP Game Report 1956 (Mansfield files).
21	71°40'N, 93°29'W, E end of Bellot Strait	1956	IX	22	1			Icebreaker *Labrador* (Mansfield files).
22	63°46'N, 82°30'W, Native Point, South Bay, Southampton Island, N. Hudson Bay	1956	XII			1 (15-20 ft)	Carcass embedded in shore ice; thought to be young bowhead.	Eskimos reported to Father Choque (Mansfield files).
23	Cumberland Sound	1956	Autumn			1	Attacked and killed by a large herd of killer whales.	RCMP Game Report 1956-57 (Mansfield files).

Table 3 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
24	Clearwater Fiord area and Cumberland Sound	1956			Many			RCMP Game Report 1956-57 (Mansfield files).
25	Near 71°05′N, 71°05′W, Scott Inlet, NE Baffin Island	1957	VI		2			U.S.C.G. Icebreaker *Westwind* (Mansfield files).
26	73°45′N, 79°50′W, Cape Hay, Bylot Island	1957	VII	4	3		Close inshore.	L.M. Tuck, Canadian Wildlife Service (C.W.S.), 1957 MS (Mansfield files).
27	Off Cape Christian, E. Baffin Island	1957	VIII	7	1			L.M. Tuck, C.W.S., aboard Can. Govt. ship *C.D. Howe* (Mansfield files).
28	Prince Regent Inlet	1957	VIII	26	1			Icebreaker *Labrador* (Mansfield files).
29	Navy Board Inlet	1957	Summer		A few			Eskimos, RCMP Game Report, 1957-58 (Mansfield files).
30	Cape Christian, E. Baffin Island	1957	Autumn		1			RCMP Game Report, 1957-58 (Mansfield files).
31	Cumberland Sound	1958-59			Some			RCMP Game Report, 1958-59 (Mansfield files).
32	Kivitoo, E. Baffin Island	1958-59			Some			"
33	Near 66°04′N, 59°28′W, Cape Walsingham, E. Baffin Island	1959	VIII	20	1		Whale identified as bowhead from a distance.	Capt. B. Blackwood, *A.T. Cameron* (pers. comm. in Mansfield files).
34	59°44′N, 62°50′W, off Cape Chidley, Davis Strait	1959	VIII	22	1		Identification unconfirmed.	Capt. B. Blackwood, *A.T. Cameron* (pers. comm. in Mansfield files).
35	Cape Christian, E. Baffin Island	1960	X		20 in a herd			RCMP Game Report, 1960-61.
36	71°14′N, 84°42′W, Easter Sound, end of Admiralty Inlet	1960			1		Carcass embedded in sand of a creek. Flesh of whale kept edible by permafrost.	Eskimos reported to J.B. Haining, HBC (Mansfield files).
37	Cumberland Sound	1960			Several		Sightings not considered unusual.	RCMP Game Report, 1959-1960 (Mansfield files).
38	Kivitoo-Broughton Island area, E. Baffin Island	1960			Several		Sightings not considered unusual.	RCMP Game Report, 1959-1960 (Mansfield files).
39	Makkovik, NE Labrador	1960				1	Part of skeleton found 8 ft deep, 330 ft inland. Skull 18 ft long.	Capt. R. Olford, D.O.T. (Mansfield files).
40	Kivitoo-Broughton Island area, E. Baffin Island	1960-1961	Summers		Several			Eskimos (Mansfield files).
41	74°41′N, 95°35′W, Cape Martyr, Cornwallis Island	1961	VII		1			Eskimos (Mansfield files).
42	Seahorse Point, E. Southampton Island, 63°47′N, 80°09′W	1961	VIII		A few		Seen every summer by hunters at Seahorse Point.	Joe Curly, Southampton Island (Mansfield files).
43	Imigen Island area, mouth of Nettilling Fjord, Cumberland Sound, 65°58′N, 66°58′W	1961	Spring		3-4		Sighted on numerous occasions.	RCMP Game Report, 1961 (Mansfield files).
44	Button Point, SE Bylot Island, and Navy Board Inlet areas	1961			Ca. 10		Largest numbers sighted by Eskimos in 25 years.	RCMP Game Report, 1961-62 (Mansfield files).
45	Off Cape Christian, E. Baffin Island	1961	IX-X				Herds of 6-20 whales seen periodically.	RCMP Game Report, 1961-62 (Mansfield files).
46	Off Term Point, NW Hudson Bay, 62°06′N, 92°30′W	1962	V	7	1			R.B. Tinling, Dept. N.Aff. and Nat. Res. (Mansfield files).
47	63°53′N, 82°30′W, Native Bay, SE Southampton Island	1962	X	13	2, ca. 40 ft		"In consort."	E.R. Mitchell, HBC (*in litt.*, 19 X 1962, Mansfield files).
48	Off Cape Christian, E. Baffin Island	1962	Autumn		6 in a herd			RCMP Game Report, 1962-63 (Mansfield files).
49	Foster Bay, NE Melville Peninsula	1963	VIII		1			Don Bissett (Mansfield files).
50	Igloolik Harbour, Igloolik Island, NW Foxe Basin	1963	VIII		1			Don Bissett (Mansfield files).
51	Off Cape Christian, E. Baffin Island	1963	Summer		Several herds			RCMP Game Report, 1963-64 (Mansfield files).
52	Button Point, SE Bylot Island, and Navy Board Inlet areas	1963			Ca. 30		Approximately 30 sightings of whales in these areas. Largest number seen by Eskimos in 25 years.	RCMP Report (Mansfield files).
53	Lake Harbour area, SE Baffin Island, in N. Hudson Strait	1963			3 large		Reported on 3 separate occasions.	"

Table 3 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
54	Cumberland Sound	1963			Many			RCMP Report (Mansfield files).
55	20 mi E of Hall Beach, E. Melville Peninsula	1963			Some			Pilots (Mansfield files).
56	72°50′N, 75°50′W, 6-8 mi off Button Point, S.E. Bylot Island	1964	V	25	1 large			Area Administrator, Pond Inlet (Mansfield files).
57	72°50′N, 77°45′W, Kaparoqtalik Glacier, S. Bylot Island	1964	VII	15	2 large		Close inshore, at foot of glacier.	"
58	72°40′N, 76°40′W, 1 mi NW of Guys Bight, NE Baffin Island, on Pond Inlet	1964	VII	27	2; 1 large, 1 small			"
59	72°40′N, 76°40′W, 1 mi NW of Guys Bight, NE Baffin Island, on Pond Inlet	1964	VII	29	1 large adult			"
60	68°31′N, 81°33′W, NE of South Ooglit Island, W. Foxe Basin	1964	VIII	7	1			Eskimo reported to D. Bissett, Area Administrator, Hall Beach, N.W.T. (*in litt.*, 9 IX 1964, Mansfield files).
61	72°40′N, 76°40′W, 1 mi NW of Guys Bight, NE Baffin Island, on Pond Inlet	1964	VIII	15	1 large			Area Administrator, Pond Inlet (Mansfield files).
62	72°50′N, 78°30′W, NE Eclipse Sound	1964	VIII	15	1 large			"
63	Near settlement of Repulse Bay, S. Melville Peninsula	1964	VIII	15	1			A.M. Millican, Regional Administrator, Churchill (*in litt.*, 29 X 1964, Mansfield files).
64	73°08′N, 80°35′W, ½ mi from Low Point, W. Navy Board Inlet	1964	VIII	16	3 large			Area Administrator, Pond Inlet (Mansfield files)
65	Vicinity Jens Munk Island, N. Foxe Basin	1964	VIII	20		1 killed	Natives reported to have sighted "as many as seven whales in one day" in the area.	Eskimos reported to D. Bissett, Area Administrator, Hall Beach, N.W.T. (*in litt.*, 9 X 1964, Mansfield files).
66	Vicinity Igloolik Island, N. Foxe Basin	1964	VIII	20	2; 1 adult, 1 calf	Attempted kill	Failed "due to a lack of gas for their boat."	"
67	59°44′N, 62°50′W, off Northern Labrador	1964	VIII	22	1		Identification uncertain.	Capt. B. Blackwood, aboard *A.T. Cameron* (Mansfield files).
68	Off Cape Christian, E. Baffin Island	1964	Summer		Several groups			RCMP Game Report, 1964-65 (Mansfield files).
69	66°08′N, 84°55′W, Frozen Strait, NE Southampton Island	1964	Summer		2			A.M. Millican, Regional Administrator, Churchill (*in litt.*, 29 X 1964, Mansfield files).
70	East of Manning Islands, 68°46′N, 80°03′W, NE Foxe Basin	1964	IX	4	1			Eskimos reported to D. Bissett, Area Administrator, Hall Beach, N.W.T. (*in litt.*, 9 IX 1964, Mansfield files).
71	73°05′N, 80°05′W, SE Navy Board Inlet	1964	IX	10	1 large			Area Administrator, Pond Inlet (Mansfield files).
72	73°05N, 80°05′W, SE Navy Board Inlet	1964	IX	11	1 large			"
73	73°05′N, 80°05′W, SE Navy Board Inlet	1964	IX	12	1 large			"

75	Pond Inlet settlement, Pond Inlet	1964	IX		1, ca. 60 ft		Whale beached at Pond Inlet settlement, returned to sea after 1½ hr.	"
76	Pond Inlet settlement, Pond Inlet	1964	X	7	1 large		Close inshore, directly in front of settlement.	"
77	Near settlement of Repulse Bay, S. Melville Peninsula	1964	X	14	1			A.M. Millican, Regional Administrator, (*in litt.*, 29 X 1964, Mansfield files).
78	West end of Fury and Hecla Strait, NW Foxe Basin	1964			1			Gerry Anders (pers. comm., Mansfield files).
79	Jens Munk Island area, N. Foxe Basin	1964			Up to 7 in one day			Jens Munk Island Eskimos, reported to D. Bissett (Mansfield files).
80	East Igloolik Island area, N. Foxe Basin	1964				1 shot, large		Father Rousselière (Mansfield files).
81	Cumberland Sound	1964			Undetermined number			Residents of Cumberland Sound, reported to RCMP, Pangnirtung (Mansfield files).
82	Near shore of Jens Munk Island, N. Foxe Basin	1965	VII	End		1 killed, 55 ft	Just after ice breakup, with 4 harpoons and floats, .303 rifle.	Noah Peewatook and 3 other Eskimos (Mansfield files).
83	Milne Inlet, Eclipse Sound	1965	VIII	3	2			D. O'Halloran (*in litt.*, n.d., Mansfield files).

Table 3 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
84	72°06'N, 80°48'W, Koluktoo Bay, Milne Inlet, Eclipse Sound	1963	VIII	8	1 large		Within 50 yd of beach at Koluktoo Bay. Sounded, exposing tail fully.	T.R. Welch and A.W. Mansfield, Fisheries and Marine Service (F. and M.S.) (Mansfield files).
85	Cumberland Sound	1965	Summer		30			RCMP Game Report, 1965-66 (Mansfield files).
86	Settlement, Clyde Inlet, E. Baffin Island	1965	Autumn		1			"
87	Near settlement at Broughton Island, E. Baffin Island	1965			1			HBC trader, reported to D.C. Foote (Mansfield files).
88	Vicinity of Broughton and Padloping islands, E. Baffin Island	1965-66			Several			RCMP Game Report, 1965-66 (Mansfield files).
89	61°40'N, 71°58'W, off Wakeham Bay, Hudson Strait	1966	VII	11-18	1		First whale seen by this Eskimo in 40 years; similar to those his father hunted with Scottish whalers.	Eskimo, reported to W.F. Shields (Mansfield files).
90	Chesterfield Inlet, NW Hudson Bay	1966	VII		1		Same kind as Eskimo's father hunted with white men 50 years before.	Pilot of M.V. *Fort Severn*, reported to W.F. Shields (*in litt.*, n.d., Mansfield files).
91	63°43'N, 61°10'W, 70 mi E of Brevoort Island SE Baffin Island, in Davis Strait	1966	VIII	9	1		No ice.	J.A. Power, aboard *C.D. Howe* (Mansfield files).
92	68°33'N, 81°08'W, 10 mi S of Hall Beach, W. Foxe Basin	1966	IX	24	1		Only spout of whale seen, apparently too large for a beluga.	W.F. Shields (*in litt.*, n.d., Mansfield files).
93	Clearwater Fiord, Cumberland Sound	1966			2; 1 large, 1 small			P. Brodie, F. and M.S. (Mansfield files).
94	Clearwater Fiord, Cumberland Sound	1965-1967			2; 1 adult, 1 calf			Eskimos (Mansfield files).
95	66°34'N, 67°33'W, mouth of Millut Bay, Clearwater Fiord, Cumberland Sound	1967	VIII	2	1 large			W. Hoek, F. and M.S. (*in litt.*, n.d., Mansfield files).
96	66°34'N, 67°33'W, mouth of Millut Bay, Clearwater Fiord	1967	VIII	3	1 small		Might be calf of above whale. Seen with pod of white whales.	W. Hoek, F. and M.S. (*in litt.*, n.d., Mansfield files).
97	Few miles W of Igloolik Island, NW Foxe Basin	1967	IX	2	2	1	Moving southwest.	J.M. Bradley, McGill University (*in litt.*, n.d. [1968], Mansfield files).
98	Off Nuwuktee Island, few miles South of Jens Munk Island, NW Foxe Basin	1967				1 killed		J.M. Bradley, McGill University (*in litt.*, n.d. [1968], Mansfield files).
99	Pangnirtung district, Cumberland Sound	1967			Ca. 15			RCMP Game Report, 1966-67 (Mansfield files).
100	Ca. 5 mi from coast of Cape Christian, E. Baffin Island	1967			Many			RCMP Game Report, 1966-67 (Mansfield files).
101	Home Bay area, NE Baffin Island	1967			Several			"
102	Clearwater Fjord, Cumberland Sound	1967			2; 1 young, 1 adult		May be same as seen in this area by Eskimos, 1965-67, W. Hoek, VIII 1967, P. Brodie, 1966.	P. Brodie, F. and M.S. (Mansfield files).
103	Few miles W of Igloolik Island	1968	VII	26	1		One of 5 sightings in area — 1 supposedly consisting of a female and calf.	J.M. Bradley, McGill University (*in litt.*, n.d. [1968] Mansfield files).
104	Kivitoo, E. Baffin Island	1968	VIII		20 in a group			Ralph Durkea, DIAND (Mansfield files).
105	West of Igloolik Island, NW Foxe Basin	1968			2; 1 adult, 1 young			Eskimo, reported by J.M. Bradley, McGill University (Mansfield files).
106	West of Igloolik Island, NW Foxe Basin	1968			2			"
107	East coast of Cape Christian, E. Baffin Island	1968			Many			RCMP Game Report, 1967-68 (Mansfield files).
108	Clearwater Fiord, Cumberland Sound	1968			2; 1 young, 1 adult			P. Brodie, F and M.S (Mansfield files).
109	Midway between Button and Resolution Islands, Hudson Strait	1969	VII	20	1, ca. 50 ft		Black whale sighted at about 100 yd, was seen to blow twice, then sounded and disappeared. Moving E.	G. Sleno, F. and M.S. aboard M.V. *Calanus* (pers. comm. 1 VIII 1972, Mansfield files).
110	20 mi E. Arlangnuk Point, NE Melville Peninsula	1969	VII	22	1		Moving NE.	H. Baubier, Eskimos (Mansfield files).
111	Kivitoo, E. Baffin Island	1969	VIII		20 in a group			Ralph Durkea, DIAND (Mansfield files).
112	Clearwater Fiord, Cumberland Sound	1969	VIII		2; 1 adult, 1 calf			"

Table 3 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
113	Winter and Vansittart Islands region NW Foxe Channel	1969			"Many"		"Many of the large Greenland Whales are being seen" in this area; "it appears that they are coming back to this area more and more."	C. Livingston, DIAND, Economic Development Officer, Repulse Bay (*in litt.*, 6 IX 1969, Mansfield files).
114	40 mi SE of Resolute, Cornwallis Island, in Barrow Strait	1979			1		With 4-5 belugas.	Duncan Grant, Bradley Air Services (*fide* H. Kiliaan, AWSR*, Mansfield files); Hay and Sergeant, 1976:Fig. 3.
115	Millut Bay, Clear-water Fiord, Cumber-land Sound	1971	VIII	12-13	1			D.E. Sergeant, F. and M.S. (*in litt.*, 24 VIII 1971, Mansfield files).
117	Vicinity Repulse Bay, Southern Melville Peninsula	1971	IX	13	2	1 killed		D. Webster, Repulse Bay (*in litt.*, 18 X 1971, Mansfield files).
118	Near 68°51'N, 81°25'W, Southern Foster Bay, NE Melville Peninsula	1971	IX	17	Some large	1 killed, ca. 40 ft		P. Van de Velde (MS report, 1972, Mansfield files); (Mitchell and Reeves, 1981: Fig. 4; 1982).
119	2 mi from Repulse Bay settlement, Southern Melville Peninsula	1971	IX	End	2-3			D. Webster, Repulse Bay (*in litt.*, 18 X 1971, Mansfield files).
120	50 mi E of Repulse Bay, in Hurd Channel, S. Melville Peninsula	1971	IX	End	3			"
121	Repulse Bay settlement, S. Melville Peninsula	1971	X	18	1 large		Whale came within a few hundred yd of shore in front of settlement. This whale seen on 2 occasions and considered by locals to be looking for her calf which had been killed.	"
122	Upper half (NW) Frobisher Bay, SE Baffin Island	1972	VIII	ca. 10		1	Attacked and killed by killer whales.	Bill Mackenzie, GNWT, (Mansfield files; pers. comm., III 1980).
123	62°32'N, 66°25'W, Frobisher Bay, SE Baffin Island	1973	IV	3-4	1 large			Can. Armed Forces, reported by Capt. T.A. Favier, Yellowknife (*in litt.*, 29 V 1973) (Mansfield files).
124	63°40'N, 66°30'W, Frobisher Bay, SE Baffin Island	1973	IV	3-4	9 medium		Comment: Lat. 63°40'N places the sighting inland on the Hall Peninsula. Lat 62°40'N would make more sense. Therefore this sighting is plotted in the general lower Frobisher Bay area, indeterminate location.	"
125	Near Native Point, SE Southampton Island	1973	V	12	1 large			Reported by E. Bowden, Game Officer, Coral Harbour (*in litt.* from W.J. Barlishen to D.E. Sergeant, 20 VII 1973, Mansfield files).
126	74°35'N, 95°31'W, 5-10 mi SW of Griffiths Island, SW of Resolute Bay, S Cornwallis Island, in Barrow Strait	1974	VII	12	3; 2 adults, 1 young (½ adult size)			W. Henderson, Dominion-Pegasus Helicopters (AWSR*) (Mansfield files); Hay and Sergeant, 1976: Fig. 3.
127	Near Pisiktarfik Island, Eclipse Sound	1974	VIII	26	2			B. Fallis, Fisheries and Marine Service (pers. comm.); Hay and Sergeant, 1976:16, Fig. 3.
128	Vicinity of Cape Fullerton, SW Roes Welcome Sound	1919	summer			2 killed 1 struck/lost		Douglas, 1975.
129	In harbour [Little Auk Bay] of Danish Island, off E coast of Vansittart Island, Frozen Strait	1921	IX	29	1			Degebøl and Freuchen, 1935:273.
131	In harbour [Little Auk Bay] of Danish Island, off E coast of Vansittart Island, Frozen Strait	1922	VIII	17	1			"
132	In harbour [Little Auk Bay] of Danish Island, off E coast of Vansittart Island, Frozen Strait	1922	VIII	19	1		Apparently the same as seen 17 VIII 1922 in the same place (see above). "Feeding."	Degerbøl and Freuchen, 1935.
133	Opposite island, off E coast of Vansittart Island, Frozen Strait	1922	VIII	23	1			"
134	In harbour of Danish Island, off E coast of Vansittart Island, Frozen Strait	1922	VIII	27	1, very small		"About twice as large as a walrus."	"
135	Hammeren, in Frozen Strait	1922	IX	13	1 small		"Undoubtedly" the same as that seen 27 VIII 1922 (see above).	Degerbøl and Freuchen, 1935:273.
136	In Hurd Channel	1922	Mid-IX		1 small		Apparently same as seen 27 VIII and 13 IX, "living in the neighbourhood."	"
139	Repulse Bay settlement	1922	summer			1 killed, "medium size"		"

* Arctic Whale Sighting Record (from Arctic Biological Station, in files of D.E. Sergeant and W. Hoek).

Table 3 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
140	Pond Inlet floe-edge	1922	VIII			1 large	1 large whale driven by killer whale(s) into an ice lead where it was killed by 2 natives with repeated fire from .44 carbine or .303 rifle. The whale yielded 1600 lbs of baleen and 20 tons (est.) of oil.	Munn, n.d.:195-196; 1932:265; Anderson, 1934:72; Degerbøl and Freuchen, 1935: 274-275.
141	At Depot Island	1923	VII	4	3 large		Had been here 1-2 days.	Degerbøl and Freuchen, 1935.
142	Whale Point, SW Roes Welcome	1923	VII	5	3 large		Appear to be the same as seen 4 VII 1923 (see above entry).	"
143	Repulse Bay ["in the fiord"]	1923	VII	20-23	6	Attempted kill	Seen over "the past few days." Eskimos attempted hunt but failed and chased whales away.	Degerbøl and Freuchen, 1935:274.
144	Repulse Bay	1923	VII	23	2; 1 large female, 1 small calf			"
145	Repulse Bay	1923	IX	3	1			"
146	In harbour of Repulse Bay	1923	IX	4	1		Could be same whale as seen 3 IX.	Degerbøl and Freuchen, 1935.
147	Repulse Bay	1923	IX	8	1			Degerbøl and Freuchen, 1935:274.
148	Repulse Bay	1923	IX	9		1 killed, small (20 ft)	Not accompanied by its mother.	"
149	Danish Island, in Little Auk Bay, off E coast of Vansittart Island, Frozen Strait	1923	X	11	1 very small		The size of a walrus.	"
151	Near Kingua (Clear-water Fiord), head of Cumberland Sound	1928			2			Anderson, 1934:72.
152	In a rocky cove in Foxe Channel, vicinity SE Southampton Island	1939	IX	2	1 large			Boyer, 1940:6.
153	Lyon Inlet, SW Foxe Basin	1940				1 killed		Manning, 1943:105.
154	Evans Strait, South-ampton Island, S side.	1930-1944 (ca.)				3 killed	"In the last few years" by Aivilik Eskimos, using whalers' equipment from ca. 1900. The carcasses were used for fox bait.	Manning, 1944:145.
157	Clearwater Fiord, head of Cumberland Sound	1971	VIII	11-12	1		The whale was seen fluking up at a range of 150 yd. Its dives lasted 15-30 min.	Reported by D.E. Sergeant, F.M.S. (pers. comm.).
158	55°05'N, 76°52'W, ca. 6 mi S of Little Whale River, E side of Hudson Bay	1967	VIII	24	1 large		Ca. 100 yd from shore. Length of exposed back est. 40 ft; black.	W. Fitzhugh, Smithsonian Institution (*in litt.* 2 I and 12 I 1973).
159	Cape Christian, NE coast of Baffin Island, also Black Bluff area	1969? (probably 1968)			Some			RCMP Game Report, to 30 VI 1969.
160	Clyde Inlet, NE Coast of Baffin Island	Probably 1969, since reported 1970			Some			RCMP Game Report, to 30 VI 1970.
161	Patricia Bay, NE Baffin Island	Probably 1970, since reported 1971			1			RCMP Game Report, to 30 VI 1971.
162	Thule Harbour, North Star Bay, NW Greenland	1943	X	23	1			Vibe, 1967.
163	South Bay, Native Point, Southampton Island, N. Hudson Bay	1956	XII	10		1 small (15-20 ft)	Found frozen in ice. Same as record no. 22.	Father J. Choque (Mansfield files).
164	In Clearwater Fiord, Cumberland Sound	1973	VIII	27	1		"A single bowhead whale has visited Cumber-land Sound and Clearwater Fiord each year for the last decade."	Wood, 1974:19.
165	Franklin Strait, near entrance of Bellot Strait	1942	VIII mid-month		1		Ca. 40 ft whale. Confusion surrounds story, so this is a questionable record.	Farrar, 1974; see Finley and Johnston, 1977; Mitchell and Reeves, 1982.
166	Cumberland Sound	1972			2			Wood, 1974:19.
167	"In water adjacent to the camp" at Ipiar-juk (just inside Pond Inlet)	1967	VII	29	2 adults			Bissett, 1968:V.2:76-77.
168	"In water adjacent to the camp" at Ipiar-juk (just inside Pond Inlet)	1967	VIII	1	1 adult, 2 "immatures"			"
169	"In water adjacent to the camp" at Ipiar-juk (just inside Pond Inlet)	1967	VIII	4	4 adults			"
170	Between Ipiarjuk and Pond Inlet settlement, Pond Inlet	1967	VIII	4	1 adult			"

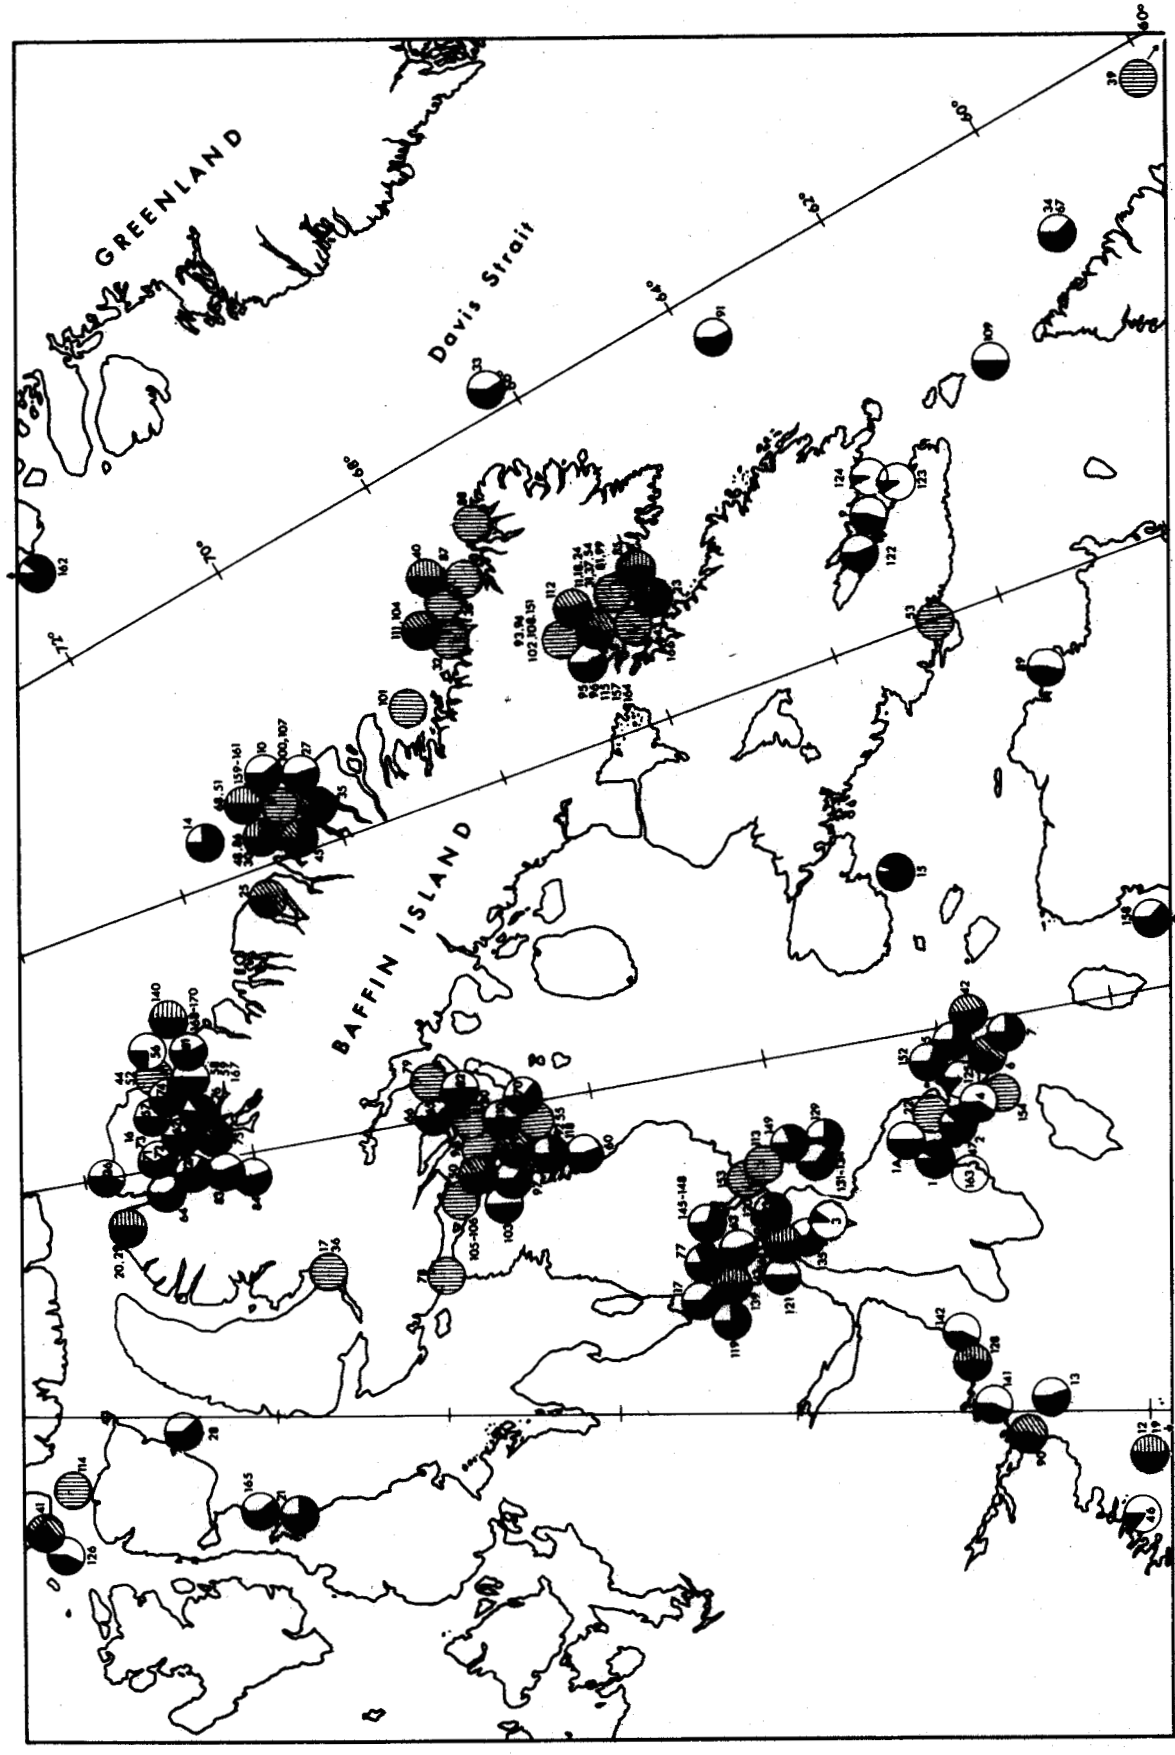

FIG. 3. Bowhead distribution, 1914-1974. Numbers refer to entries on Table 3.

TABLE 4. Occurrences of the bowhead whale in the eastern Canadian Arctic, 1975-1978

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
2	Near 78°43'N, 74°07'W, off Cape Sabine, eastern tip of Pim Island, Smith Sound	1975	V	23	1		About 200 m offshore, reportedly moving north.	Andreas Züst, ETH, Zürich. (AWSR*).
3	Near 73°40'N, 83°40'W, off Cape Joy, Admiralty Inlet	1975	VI	5	1 small		Motionless at surface, then disappeared after circled by helicopter. Two polar bears were on ice nearby.	K.Hay, Fisheries and Marine Service (F. and M.S.); Hay and Sergeant, 1976: Fig.1.
4	Near 73°45'N, 89°25'W, 20 miles ESE of Port Leopold, Somerset Island	1975	VI	5	1 large		Dove after being circled by helicopter.	K. Hay, F. and M.S.; Hay and Sergeant, 1976:Fig.1.
5	Between Cape Clarence and Prince Leopold Island, eastern Barrow Strait	1975	VI	6	1		Near the edge of fast ice near Prince Leopold Island. Whale dove before helicopter reached it.	K. Hay, F. and M.S.; Hay and Sergeant, 1976: Fig.2.
6	E side of Prince Leopold Island, eastern Barrow Strait	1975	VI	6	1		Blew 5-6 times, making shallow dives between blows, sounded, then was lost from view, moving north.	D.N. Nettleship, Canadian Wildlife Service (C.W.S.) (AWSR*; *in litt.*, 1 XII 1977).
7	72°40'N, 75°00'W, ESE of Bylot Island	1975	VI	11	2		Not positively identified as bowheads. Off fast ice, in about 5/10 small floe ice.	P.R. Young, Ice Observer, AES, (AWSR*).
8	73°03'N, 86°23'W, W side of Admiralty Inlet	1975	VII	23	1 35-40 ft		100 yd offshore, moving north at ice edge.	D.W. Doidge and R. Adams, F and M.S.; Hay and Sergeant, 1976:Fig.4.
9	Off Kakiak Point, W side of Admiralty Inlet	1975	VII	26	1		Among broken ice pieces. Moving south.	D.W. Doidge and R. Adams, F. and M.S.; Hay and Sergeant, 1976:Fig.4.
10	72°25'N, 86°10'W, NW of Yeoman Island, S. Admiralty Inlet	1975	VII	27	3		Moving south.	Eskimo hunters, Arctic Bay (source uncertain).
11	Southern Creswell Bay, Somerset Island	1975	VII	27	1 large			Finley, 1976:163-164, Fig. 37.
12	Near 72°41'N, 86°40'W, off Kakiak Point, W side of Admiralty Inlet	1975	VII	28	2		These 3 whales (#12 and 13) may be the same animals seen in this area by Arctic Bay hunters one day earlier (#10). Moving northeast.	B. Fallis, F. and M.S. (pers. comm.).
13	Near 72°44'N, 85°55'W, off Peter Richards Island, S. Admiralty Inlet	1975	VII	28	1		Moving north.	B. Fallis, F. and M.S. (pers. comm.).
14	Off Giants Castle, W side of Admiralty Inlet	1975	VII	30	1			D. W. Doidge and R. Adams, F. and M.S.; Hay and Sergeant, 1976: Fig. 4.
15	Near 72°49'N, 91°54'W, Fury Beach, SE Somerset Island, Prince Regent Inlet	1975	VIII	2	1		Lifted flukes on diving; dark in colour and ca. 30 ft long. Moving north.	J. Netterville, G.S.C. (AWSR*); Finley, 1976:164, Fig. 37.
16	Off Kakiak Point, W side of Admiralty Inlet	1975	VIII	8	1		Moving north at the edge of broken ice, 100-200 yd offshore.	D. W. Doidge and R. Adams, F. and M.S.; Hay and Sergeant, 1976: Fig. 4.
17	Near 75°48'N, 97°50'W, Goodsir Inlet, E. Bathurst Island	1975	VIII	1-10	1, 35-40 ft		Locality unconfirmed.	G.S.C. personnel, AWSR*.
18	Southern Creswell Bay, Somerset Island	1975	VIII	10	3 large		Pan ice.	Finley, 1976:164. Fig. 37.
19	72°43'N, 86°44'W, W side of Admiralty Inlet	1975	VIII	20	2; 1 large 1 smaller		Moving north.	D. W. Doidge and R. Adams, F. and M.S.; R. Reeves; Hay and Sergeant, 1976: Fig. 4.
20	Southern Wellington Channel	1975	VIII	22	1 large			Finley, 1976:164, Fig. 37.
21	1 mi E of Vista River, near 72°43'N, 86°44'W, W side of Admiralty Inlet	1975	VIII	25	1 large			D. W. Doidge and R. Adams, F. and M.S.; Hay and Sergeant, 1976: Fig. 4.
22	York Sound, SW side of Frobisher Bay	1975	VIII		1		Large black whale chased by several killer whales.	Bill Mackenzie (AWSR*; pers. comm., March 1980); Mitchell and Reeves, 1982.
23	Repulse Bay Area, Southern Melville Peninsula	1975	summer			1 (30 ft) killed		Eskimo hunters, reported by H. Trudeau and D.H. Dowler, F.M.S., Yellownife; Mitchell, 1977.
24	Near 65°50'N, 67°50'W, Netilling Fiord area, western Cumberland Sound	1975	End VIII to early IX		2; 1 adult, 1 young		Hunter's father and grandfather had never seen bowheads in this area before.	R. Redhead, Fish and Wildlife Officer, Pangnirtung (*in litt.*, 16 X 1975).
26	Near 73°44'N, 82°49'W, off Cape Charles Yorke, N. Borden Peninsula	1975	X	2	1		Moving east.	"
27	Coral Harbour Area, SE Southampton Island	1975			At least 1	Attempted kill	At least 1 whale known struck but lost.	Eskimo hunters, reported by M.C. Mercer, F. and M.S.; Mitchell, 1977.
28	Igloolik-Hall Beach area, NW Foxe Basin	1975			At least 1	Attempted kill	At least 1 whale known struck but lost.	"

* Arctic Whale Sighting Record (from Arctic Biological Station, in files of D.E. Sergeant and W. Hoek).

65	Near 72°39′N, 76°38′W, 2 mi NE of Guys Bight, NE Baffin Island	1976	VII	24	1		Moving south in broken ice at the floe edge.	K. Hay, F and M.S. (AWSR*).
66	Near 74°01′N, 83°33′W, eastern Lancaster Sound	1976	VII	26	1			Johnson *et al.*, 1976:71.
67	Near 74°08′N, 83°33′W, eastern Lancaster Sound	1976	VIII	8	1			"
68	Off Kakiak Point, W coast of Admiralty Inlet	1976	VIII	28	1		Moving south.	R. Greendale, F and M.S. (AWSR*).
69	Near 74°48′N, 80°01′W, mouth of Bethune Inlet, SE Devon Island	1976	VIII	29	1			Johnson *et al.*, 1976:71.
70	Near the tip of South Spit, E coast of Prince Leopold Island	1976	IX	5	3		Three whales sighted together moving north. Two were about the same size, the third slightly smaller. They surfaced about 10 times before being lost from view, moving fast, not sounding. Ice cover 30%.	E. Greene and D.N. Nettleship, C.W.S. (*in litt.*, 1 XII 1977; AWSR*).
71	Near 73°57′N, 83°00′W, eastern Lancaster Sound	1976	IX	6	1			Johnson *et al.*, 1976:71.
72	In bay W of South Spit, S coast of Prince Leopold Island	1976	IX	7	1		Whale seen moving east in bay west of the South Spit. It dove, remained submerged for 5 min, resurfaced, circled the bay, then turned back heading west; 40% pan ice.	E. Greene and D.N. Nettleship, C.W.S. (*in litt.*, 1 XII 1977;AWSR*).
73	74°01′N, 87°00′W, about 15 mi off Brodeur Peninsula, western Lancaster Sound	1976	IX	12	2-3		Whales were swimming among narwhals, moving northeast.	E. Greene and D.N. Nettleship, C.W.S. (*in litt.*, 1 XII 1977; AWSR*).
74	Near 69°08′N, 66°45′W, Cape Henry Kater, eastern Baffin Island	1976	IX	14	3		Two whales were together, the third 4-5 miles north, all moving south.	P. Rosseau, Fish and Wildlife Officer, Pangnirtung (AWSR*).
75	W of Arctic Bay, in Admiralty Inlet	1976	IX	22	2		Moving north.	Anon. MS., n.d. [1976]:75.
76	5-10 mi N of Henry Kater Peninsula, eastern Baffin Island	1976	IX	26	15 large		In a loose aggregation.	Webb, 1976:Pt.3:19, Map 4.
77	About 30 mi WNW of Kivitoo, eastern Baffin Island	1976	IX	26	2 large			Webb, 1976:Pt.3:19, Map 6.
78	About 23 mi WNW of Kivitoo, eastern Baffin Island	1976	IX	26	2 large			"
79	1-5 mi N of Henry Kater Peninsula, eastern Baffin Island	1976	IX	30	11 large		Probably the same group of 15 seen in this area 4 days earlier (#76), having moved southward.	Webb, 1976:Pt.3:19, Map 4.
80	About 5 mi E of Cape Raper, eastern Baffin Island	1976	IX	30	1 large			"
81	Near 69°25′N, 67°00′W, inshore and N of Henry Kater Peninsula, E of Aulitiving Island, eastern Baffin Island	1976	X	Early	20 (est.)			Connors, pilot, Bradley Air Services (AWSR*).
82	Mouth of a bay 12 mi NW of Cape Dyer, eastern Baffin Island	1976	XI	2-5	4-5		In a productive nearshore area, and thought to be recent arrivals to the area after a southward migration.	Joe Kreke, Apex Helicopters, *fide* Webb, 1976: Pt.3:19, A2.
83	Near Allen Island, 10 mi south of Robinson Sound, SE Baffin Island	1977	IV	3-9	2; 1 adult, 1 young			Hunters and Trappers Assoc. report (source uncertain).
84	Near 74°25′N, 85°34′W, central Lancaster Sound	1977	V	27	3-4			*Fide* D.W. Doidge, F. and M.S., aboard *Louis St. Laurent* (pers. comm.).
85	Near 74°25′N, 85°37′W, central Lancaster Sound	1977	V	27	1			"

Table 4 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
86	Near 74°25'N, 85°45'W, central Lancaster Sound	1977	V	27	1			*Fide* D.W. Doidge, F. and M.S., aboard *Louis St. Laurent* (pers. comm.).
87	74°25'N, 85°51'W, central Lancaster Sound	1977	V	27	3			"
88	74°21.5'N, 88°13'W, western Lancaster Sound	1977	V	28	2			"
89	74°23.3'N, 88°39'W, western Lancaster Sound	1977	V	28	2			"
90	Near 74°20'N, 90°02'W, immediately NW of Prince Leopold Island	1977	VI	2			One whale, identification uncertain, seen within 3 mi of coordinates given.	D.N. Nettleship, C.W.S. (*in litt.*, 1 XII 1977).
91	74°16'N, 81°00'W, entrance to Lancaster Sound	1977	VI	4	3-4 large		Large whales, black with some white underneath, V-shaped blow, no dorsal fin. Observed at 500-1000 yd. Small hole in heavy ice. Moving southwest.	J.D. Bradford, Dept. Fisheries and Env., Ottawa (AWSR*).
92	59°16'N, 56°50'W, Labrador Sea	1977	VII	31	2 large		V-shaped blow. Not positively identified as bowheads. Moving east.	R. McGregor, C.C.G.S. *Louis St. Laurent* (AWSR*).
93	67°53'N, 57°45'W, about 110 mi NE of Cape Dyer, in Davis Strait	1977	VIII	2	1 large		Large (55-60 ft) black whale seen in "bergy" water. Moving east-southeast.	P.H. Heck, Atmospheric Environment Service (AES) (AWSR*).
94	Near 74°22'N, 93°00'W, 30 mi SE of Resolute Bay, in eastern Barrow Strait	1977	IX	20	1			D.N. Nettleship, C.W.S. (*in litt.*, 1 XII 1977).
95	Erebus and Terror Bay between Cape Riley and Beechey Island, eastern Barrow Strait	1976	VII	19	3; 1 large, 2 smaller		Swimming nose-to-tail in lead.	P. Severs, M. Burnip, P. Lane, C. Parmenter (Mitchell files, 23 VII 1976).
96	Abandonment Bay, NE side of Cornwallis Island	1976	VII	23 (ca.)	Skull found			Bob O'Connor, Aero-Arctic Ltd., Yellowknife, (Mitchell files, 23 VII 1976).
97	63°18'N, 63°58'W, near Brevoort Island, SE coast of Baffin Island	1977	IX	14	1		Within 200 m of shore; photographed.	Allen and Conover, 1978a:4-15, Table 5-49, Pl.IV.
98	64°59'N, 63°20'W off Cape Mercy, mouth of Cumberland Sound, SE Baffin Island	1977	IX	14	1		Within 200 m of shore.	Allen and Conover, 1978a:4-15, Table 5-49.
99	Western Kennedy Channel, 20 km S of Cape Defosse, Judge Daly Promontory, NE Ellesmere Island (observed from 81°08'N, 66°20'W)	1978	VII	22	10-20		Large black whales in groups of 2-4, no dorsal fins, very large (>20 ft, likely >40 ft). Whales were slow-moving, seemed to "be enjoying still water and open area free of sea ice for at least 20 km." Moving north. Observers were here 5 yr but never saw bowheads in this area before. Davis and Koski (1980) indicate only 10-15 individual whales in sighting.	J. England, Dept. of Geography, Univ. of Alberta (AWSR*); Davis and Koski, 1980:442; Koski and Davis, 1979:133.
100	Clearwater Fiord, head of Cumberland Sound	1978	IX	17	1 small			B. Kemper, pers. comm., 2 X 1978.
101	Cape Adiar, NE coast of Baffin Island	1978	13 IX - 7 X		41		Migrating southeast within 1.5 km of coast.	Davis and Koski, 1980: Koski and Davis, 1979:128-130.
102	Along E coast of Bylot Island	1978	X	7	8			Davis and Koski, 1980; Koski and Davis, 1979:130.
103	62°25'N, 61°33'W, 150 km (est.) E of Loks Land, entrance to Frobisher Bay, in Davis Strait	1978	III	28	1		In heavy pack ice associated with leads.	Conover, Parsons and Orr, 1979:5-21, Fig. 5-35.
104	61°00'N, 63°07'W, 90 km (est.) SE of Resolution Island, entrance of Hudson Strait	1978	III	28	3; 2 large, 1 small		"The three animals seen together were first observed nose to nose...the largest whale was 2 to 3 m longer than the second whale which, in turn, was closely associated with a smaller animal. The smaller whale appeared about ⅔ to ¾ the body length of the second whale. The closer association of the two smaller whales suggested they were a female and calf. Even as the larger animal moved off, the smaller whale kept in close contact with the second largest whale." In heavy pack ice associated with leads.	"
105	60°39'N, 66°W, mouth of Hudson Strait	1978	IV	22	2; 1 large, 1 small		Probably female and calf.	Conover, Orr and Parsons, 1979: Fig. 4-54, Table 5-8-1.

Table 4 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
106	65°39′N, 62°40′W, mouth of Hoare Bay, SE Baffin Island	1978	IV	23	1			Conover, Orr and Parsons, 1979: Fig. 4-54, Table 5-8-1.
107	65°10′N, 64°58′W, in Cumberland Sound, near mouth	1978	IV	24	1			Conover, Orr and Parsons, 1979: Fig. 4-55, Table 5-8-1.
108	61°00′N, 64°06′W, mouth of Hudson Strait	1978	IV	25	1			"
109	60°58′N, 66°00′W, mouth of Hudson Strait	1978	V	7	1			Conover, Orr and Parsons, 1979: Fig. 4-56, Table 5-8-2.
110	65°20′N, 65°38′W, central Cumberland Sound	1978	V	13	1 large		Large whale but identification as bowhead uncertain.	"
111	64°50′N, 65°01′W, near mouth of Cumberland Sound	1978	V	13	1			"
112	65°07′N, 65°13′W, south-central Cumberland Sound	1978	VI	14	1			Conover, Orr and Parsons, 1979: Fig. 4-61, Table 5-8-3.
113	60°48′N, 57°46′W, southern Davis Strait	1978	VII	26	2, 40-45 ft		2 black whales seen. Ice-free, light sea, 5-ft waves, water temp +7°C, air temp. +8.1°C, wind southerly 10 kts, visibility 10 mi. [Identification uncertain.]	P.H. Heck, AES, C.C.G.S. *d'Iberville* (AWSR*).
114	5 mi E of Pond Inlet settlement, Pond Inlet	1978	VIII	8	3		Near ice in Pond Inlet, moving west, "surface feeding".	R.R. Wallace, Petro-Canada, M.V. *Theron* (AWSR*).
115	73°57′N, 88°35′W western Lancaster Sound	1978	VIII	12	1 ca. 50 ft		Greyish black, white patch, tail flukes observed. 3/10 first-year ice with few multi-year floes; first-year ice 38-61 cm thick. Water temp. -0.6°C, air temp. +1.2°C, overcast, winds E 10 kts, very light sea, waves < 1 ft.	P.H. Heck, AES, C.C.G.S. *d'Iberville* (AWSR*).
116	Cumberland Sound, between Kekerten Island and Kipisa	1979	VI	23	5-6, at least one a calf		First whale seen had small (12-22 ft) brownish calf on right side. This whale appeared to be resting on surface in calm water. Second whale seen 200 yd N of first. Size 50-55′, also appeared to be resting on surface, large part of body exposed. Another 2 whales seen in same lead, 150-200 yd W of second whale. Possibly calf with one whale since slight disturbance in water next to it. These last whales of similar size, 40-45 ft, separated by 30-50 yd of open water. No other whales seen in area. All whales seen in open leads in ice, with edge of ice floe ½ mi (est.) west of this sighting area. Open water to NW corner Cumberland Sound. SE of whales were ice and open leads. Visibility 30 mi, west wind at 15-18 mph, sky clear. First whale seen to blow, and flukes exposed.	Ken Birss, Bradley pilot, pers. comm., IX 1979.
117	63°20′N, 64°07′W, off southern tip of Brevoort Island, SE Baffin Island coast	1978	IX	7	1			Conover, Orr and Parsons, 1979: Fig. 4-69, Table 5-8-6.
118	63°44′N, 63°55′W, off Brevoort Island, SE Baffin Island coast	1978	IX	26	1			Conover, Orr and Parsons, 1979: Fig. 4-73, Table 5-8-6.
119	63°17′N, 63°59′W, off southern tip of Brevoort Island, SE Baffin Island coast	1978	IX	26	1			"
120	Entrance of Clearwater Fiord, head of Cumberland Sound	1978	IX	17	1		This sighting may be the same as that noted previously on this date in the same area (Entry No. 100); the above sighting was of a calf.	Conover, Orr and Parsons, 1979: Fig. 4-71, Table 5-8-6.
121	63°43′N, 64°21′W, off SE Baffin Island coast	1978	IX	17	1			Smith *et al.*, 1979:52.
122	63°54′N, 64°16′W, off SE Baffin Island coast	1978	IX	17	2; 1 large, 1 small			"
123	Ca. 61°N, 64°30′W, between Resolution Island and Button Islands, mouth of Hudson Strait	1977	IV	2	1 "whale" unidentified			Allen and Conover, 1978b:9, Fig. 4.
124	Peel Sound, 5 km off Cape Brodie, N Prince of Wales Island	1976	IX	4	1			Finley and Johnston, 1977:27, Fig. 8.
125	Between Atangmik and Napassoq, W. Greenland	1956	III			1 small killed		Freuchen and Salomonsen, 1958: 107; Anon., 1965.

Table 4 (continued)

Key No.	Locality	Time of Occurrence Year	Mo.	Day	Sighting	Mortality	Remarks	Source
126	1 mi off Ekwan Point, NE of Attawapiskat, James Bay, on a trip to Akimiski Island	1978	VII	11	1		About 200 belugas seen in a line approximately 1 mi long on the surface. Many young in the pod, also 1 bowhead. Moving northeast.	J. Crawford, A.F.O.H. helicopter pilot, M.O.T., Ottawa (AWSR*).

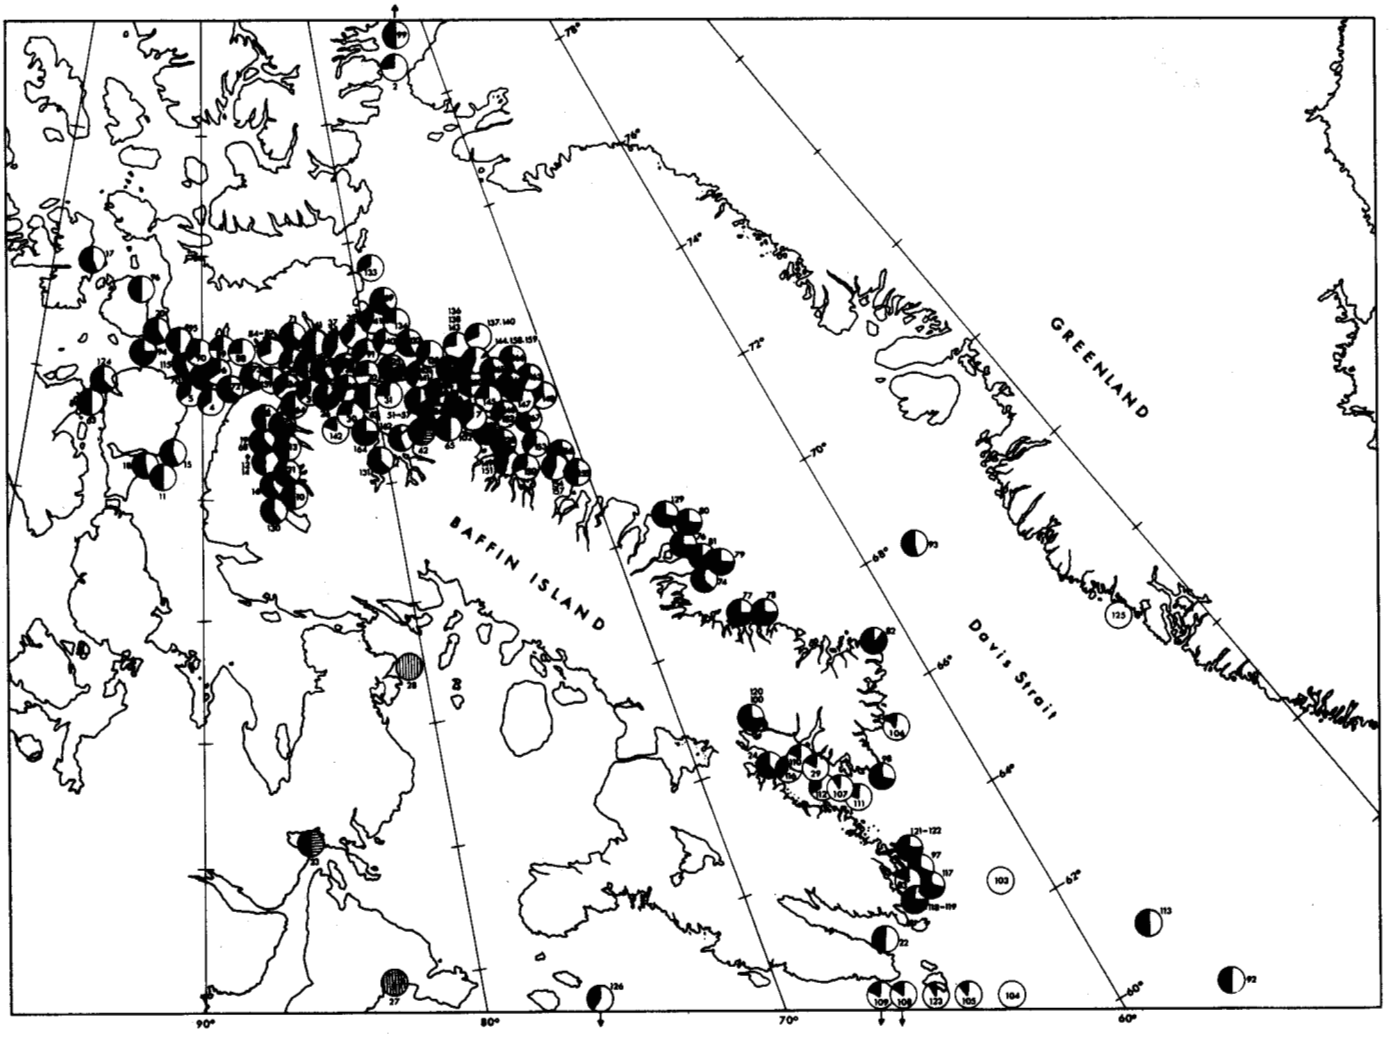

FIG. 4. Bowhead distribution, 1975-1979. Numbers refer to entries on Table 4.

RESULTS AND DISCUSSION

As Southwell (1887:187) stated: "from long experience of the habits and migration of the Whales, the regularity of which is remarkable, the Whalers know precisely where they should be found, under favourable circumstances, at certain definite periods; and not only so, but also the age and size which may be expected." We accept this premise, with the caution that climatic and technological limitations usually prevented the whalers from following the bowhead throughout the entire year. Their opinions about the whales' migratory behavior and wintering grounds, especially, were often based on inference and speculation, which nevertheless came from direct observations and efforts to hunt whales (Fig. 5). It is unrealistic to contemplate a research program today that would match the enormous searching effort by the nineteenth-century whalers. These men, some of them well informed and literate (e.g. Scoresby, 1820, 1823; Gray, 1888), collected a large sample of specimens, and those who recorded the size, sex, and length of "bone" (whalebone or baleen) of the whales they captured created a diffuse but invaluable set of data for modern whale biologists (Tables 5 and 6).

The nineteenth-century whalers, upon whose authority we have based most of our generalizations about historic bowhead distribution, established itineraries enabling them to catch bowheads at different seasons in different parts of the Eastern Arctic. These itineraries reflected not only the state of

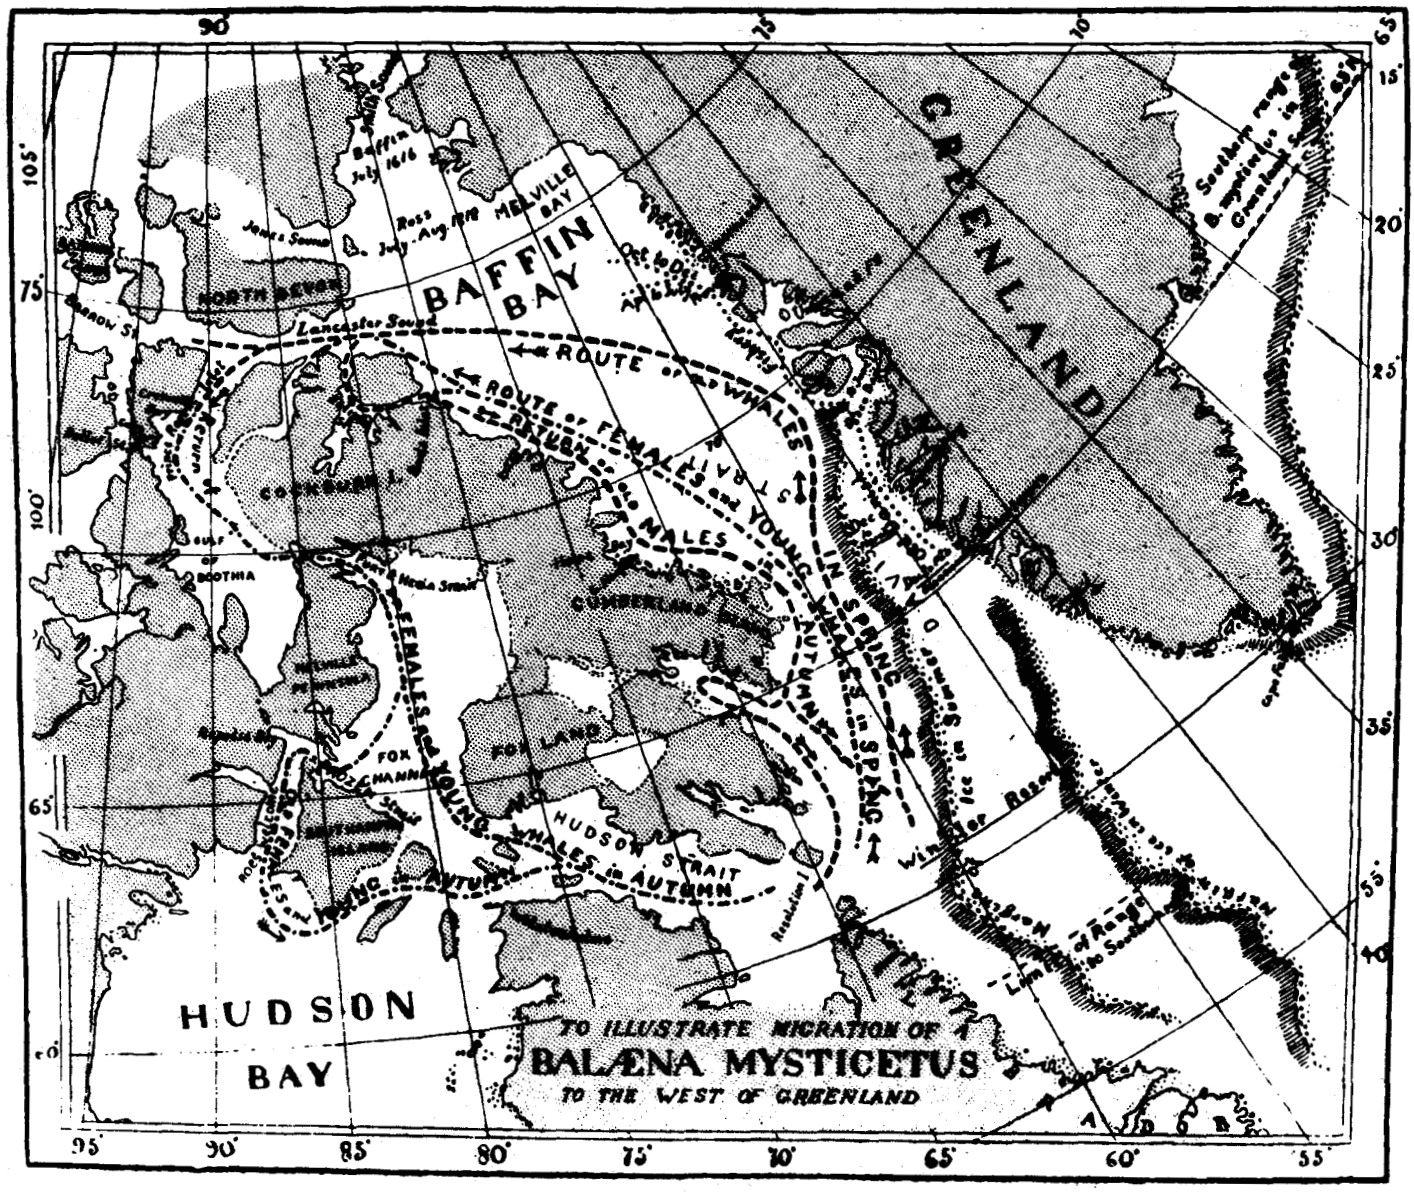

FIG. 5. This figure represents Thomas Southwell's (1898, Plate XII) understanding of the migration pattern of bowhead whales west of Greenland. It is based on nineteenth-century literature and on information received by Southwell directly from whalers. Thus, it contains some well documented insights. However, Southwell's chart reflects an unwarranted certainty about several aspects of the migration. For example, the impression that Repulse Bay and Roes Welcome Sound are supplied with bowheads exclusively by a segregated component of the Davis Strait stock during its annual circumnavigation of Baffin Island is almost certainly erroneous. Moreover, the indications that only old whales migrate along the Greenland coast in spring and that only old males migrate along the east coast of Baffin Island in autumn are probably, at best, only partially accurate.

TABLE 5. Catch of bowheads by *Cumbrian* of Hull in Davis Strait and Baffin Bay during 1823 (from Lubbock, 1937:254). The vessel's logbook for 20 August recorded: "Our success was beyond the most sanguine expectations, having on board as many whales as the ship could safely carry, 23 in number, yielding probably about 245 tons [of oil]" (Lubbock, 1937:255.).

TABLE 6. Record of bowhead whales captured by *Cumbrian* of Hull in Davis Strait/Baffin Bay during 1827 season (from Lubbock, 1937:273). The 18 bowheads produced a total of 372 casks or 280 tons of oil ($\bar{x}$ = 15.6 tons), described by Lubbock (1937:271) as "the largest cargo in the annals of Arctic whaling."

knowledge as to the bowhead's distribution and movements but also the severe limitations on navigation imposed by ice conditions and day length. Below, we outline the pattern of whaling activity and identify the major whaling grounds.

West Greenland (Shore-Based)

From approximately 1719 onwards an international fishery for bowhead whales was conducted in Davis Strait and Baffin Bay (Scoresby, 1820:V.2:382-390; Ross, 1979). An important component of the fishery was centered in inshore waters of western Greenland and was prosecuted from Danish shore stations or "factories" (Eschricht and Reinhardt, 1861, 1866). In their landmark study of the distinction between the bowhead whale and the right whale, *Eubalaena glacialis*, Eschricht and Reinhardt reviewed bowhead distribution based on records kept by the Danish colonial administration.

The whaling occurred mainly between 60°N and 73°N latitude, a stretch of coastline covering about 200 Danish miles. It began during the early 1700s, and by 1860 only the station near Holsteinsborg remained active (Eschricht and Reinhardt, 1866:13).

The usual limits of the bowhead's distribution were considered to be Upernavik (ca. 73°N) in the north and Sukkertoppen (ca. 65-66°N), sometimes called "Sugar Loaf" by the British whalers (Barron, 1970:121), in the south. Although they were aware of sightings by Baffin (Ellis, 1748:52; Pennant, 1784-87:V.1:186) in Wolstenholme Sound and the entrance to Smith Sound (ca. 78°N) and by Ross (1819:V.1:88,154) at 75-76°N off northwest Greenland, Eschricht and Reinhardt (1861, 1866) had no knowledge of bowheads being seen or caught consistently in the great ice-choked bight called Melville Bay. Brown (1868:544) had "only heard of one instance in which it [the bowhead] has been seen as far north as the Duck Islands near the entrance of Melville Bay, and even for a considerable distance south of that it can only be looked upon as an occasional straggler." Several were seen early in September at about 75°N, 64°W (M'Clintock, 1863:114-115). Brown believed the whales seen in summer in northern Baffin Bay and Smith Sound went there only after having first crossed to the west side of Davis Strait. It is generally believed that bowheads rarely occur further north than 75°N latitude on either side of Baffin Bay

(Southwell, 1898; but see Lubbock, 1937:211; Fisher, 1819:93-94).

Brown (1868) and Eschricht and Reinhardt (1866) agreed that bowheads were seldom seen farther south along the Greenland coast than Sukkertoppen, the most southerly whaling station. Those that did reach these latitudes were usually young individuals (note, for instance, the whale taken in March 1956 at Atangmik and Napassoq [Freuchen and Salomonsen, 1958:107; Anon., 1965]).

There is evidence of a marked seasonal migration along the Greenland coast. During most of July and August bowheads are not to be found off western Greenland between 60° and 73°N latitude (Eschricht and Reinhardt, 1866). They appear off Upernavik during late September or October and remain through November and early December. At this time whales begin to appear near Godhavn and elsewhere in Disko Bay, where they usually remain until at least early May and usually into the first half of June. Their arrival at Holsteinsborg (near 67°N) can be as late as early January, and they usually disappear from here in March (see Rink, 1877:122,127). Bowheads were regularly caught at Sukkertoppen during December through February. Umanak Fiord, north of Disko Bay, is covered with ice for six months of the year, but bowheads make their appearance here in June and sometimes into early July. Bowheads are seen again at Upernavik from April to July.

Eschricht and Reinhardt (1866) considered "the motion and drift of the ice in Baffin's Bay" to be the main factor controlling bowhead distribution along the Greenland coast. The whale's "arrival at the coast is in the most remarkable manner contemporaneous with the arrival of those huge masses of drifting ice which, issuing from the northern and north-western part of Baffin's Bay, are known in Greenland by the name of the 'west-ice'" (Eschricht and Reinhardt, 1866:11). These authors had little doubt that "the whale comes from the north or north-west to its winter stations" (1866:9), suggesting a relationship between the bowheads wintering along the coast of Greenland and those found off Pond Inlet and in Lancaster Sound and adjacent waters during summer (see below). Brown (1868:543) believed most of the bowheads from the east side of Davis Strait crossed westward in the "middle ice" during June at about the latitude of Svartenhuk (ca. 71°30'N).

West Greenland (Pelagic) - "Disko Water" or "Black Hook Water"

Much of the Davis Strait whaling conducted by Dutch, German, and British vessels was centered on grounds near the west coast of Greenland, especially prior to 1817 when the first crossing of Melville Bay by whalers opened up the "west water" fishery of the Lancaster Sound region (see below). British vessels continued to visit these grounds during the second half of the nineteenth century, often after spending an early spring season sealing at Jan Mayen or Newfoundland. Some vessels prosecuted the "south-west fishing" off Resolution (for bowheads and later for bottlenose whales; see below) before proceeding to the Greenland coast; others went there directly, sometimes reaching Disko Island in March (M'Clintock, 1860:94). The latter were generally more likely to arrive in time to catch whales (see Lubbock, 1937:277).

An example of a "season on the east side" (Barron, 1970:12) is the cruise of the *Abram* of Hull in 1839 (*Abram*, 1839). After departing from Hull on 11 March, the *Abram* was at 67°43'N latitude off the Greenland coast on 26 April. The next day she made her first lowering for a bowhead and thence began cruising for whales "among the bay floes." With at least five other British vessels, the *Abram* remained off Disko Island until mid-May. The second half of the month was spent in the vicinity of Hare Island, lowering occasionally for whales. Although her aim was to reach the "Northern Passage to the NWest Coast of America" (i.e., the usual route via the "north water" to the Lancaster Sound region), the *Abram* and much of the fleet failed to clear the "middle pack" of Melville Bay. On 21 July she "bore away for the south fishing ground."

Barron (n.d. [1890], 1970 [1895]) had long experience on the east side whaling grounds. The *Truelove* would usually sail from Hull in March and reach the western coast of Greenland during the first half of April. Often her arrival at Whale Fish Island in Sydøstbugt ("S.E. Bay") was about a week too late, the natives informing the crew that many whales had been present before the ship's arrival (Barron, 1970:53,131). From Sydøstbugt the vessel would cruise in the "offing", or offshore in the pack ice. There was a saying among the whalemen: "With Riff Koll Hill and Disco dipping there you will see the whale fish skipping" (Barron, 1970:47). During the first half of April the "offing" about 60 mi from Riff Koll and 65-70 mi from Disko was considered a productive whaling ground (also see Lindsay, 1911:108). During spring there was a "good fishing station" just north of 68°N, "a few leagues from land" (Scoresby, 1820:V.2:387).

Barron (1970:93) believed the area between Fortune Bay and Godhavn to be a good early-season ground. As the season wore on, the vessels would head for Umanak Fiord ("N.E. Bay"), often cruising around Hare Island en route (1970:49,53,131). "Directly any water makes its appearance in Omenak Fiord ... the whales are seen there, and at other times in the offing, according to the state of the ice" (1970:181,18-19). Svartenhuk ("Black Hook") was an important landmark. After the whales had left the grounds off Svartenhuk, the whalers generally would begin their arduous advance toward the "north water", and little whaling would occur until the "west water" was reached. The "offing" of Svartenhuk constituted "fine whaling grounds in the month of May", but it was "the last [i.e. most northerly] on the east side of Davis Strait" (Barron, 1970:64).

Among the areas considered especially productive in late spring and early summer were, in addition to "S.E. Bay" and "N.E. Bay", Jacob's Bight, Hingston Bay, Horn Sound, and the ice west of Hare and Disko islands (Scoresby, 1820:V.2:387; Leslie *et al.*, 1835:440; Gray, 1888; Sutherland, 1852:V.1:44,51; Lubbock, 1937:243). By the early nineteenth century these grounds had become depleted

— "of late they have afforded but few whales" (Scoresby, 1820:V.2:387).

After about 1850 the British whalers began to lose confidence in the "east side". Sutherland (1852:V.1:41) called Umanak Fiord ("N.E. Bay") a "famous resort for whales" that had become "almost entirely deserted". He said the same of Hingston Bay (1852:V.1:164). Although bowheads certainly continued to be caught off western Greenland, they were "not nearly so plentiful as formerly, when the Davis-Strait whaler generally pursued his business on this portion of the coast; ... they are now so few that they have generally gone north before the arrival of those ships which have first proceeded to the Spitzbergen [Jan Mayen] sealing" (Brown, 1868:544). By the end of the century, Disko Bay was referred to as a place "where once a great fishing was carried on" (Gray, 1888; and see Southwell, 1898).

"South-West Fishing"

Rather than sailing directly to the Disko Bay area in spring, many British whalers began their season with a visit to the "south-west fishing". Markham's (1875) account is one of several allowing us to trace such an itinerary (Fig. 6; Table 7).

The *Arctic* sailed from Dundee on 3 May 1873, several days later than Captain Adams had intended. By 15 May she was at the "south-west fishing" in heavy pack ice east of Resolution Island. By all accounts this phase of the fishery was among the most difficult and unrewarding (Scoresby, 1820:V.2:389). As Gray (1888) put it: "Although numbers of large whales are usually seen, yet, owing to the boisterous weather and the compact nature of the ice, the fishing is seldom very successful."

Perhaps the best that can be said of this fishery is that the whales taken were often large (Lubbock, 1937:262; Duncan, 1827:7,9). For example, the *Cumbrian* caught eight bowheads in 1827 at the "south-west fishing", their bone averaging 10 ft 11 in. (Table 6).

The "south-west fishing" could begin as early as the first of April and last through June (Parry, 1821:302; Duncan, 1827:4-5,10-13; Jardine, 1837:V.6:96; Eschricht and Reinhardt, 1866:15; Lubbock, 1937:271-272,277). By the beginning of May "the fish at the South-West sometimes retire into the ice or to the northward"; some could still be caught there as late as July, "but only in icy situations, near the Labrador coast" (Scoresby, 1820:V.2:388). The grounds centered at about 61-62°N latitude and 60-64°W longitude, or generally at the mouth of Hudson Strait, along the southeast coast of Baffin Island to Cumberland Sound, and along the northeast coast of Labrador. Barron (1970:75) claimed the grounds actually began at 56°30'W longitude, or about 240 mi east of Resolution Island. In later years, the "south-west fishing" grounds were used for bottlenose whaling at the same season (Lindsay, 1911; Savours, 1960).

After taking a large male bowhead on 23 May, the *Arctic* left the "south-west fishing" and headed straight for "Lievely" (Godhavn), on the south end of Disko Island, where she arrived on 1 June (Markham, 1875). For most vessels that had tried the "south-west fishing" this was really just a way-station en route to Melville Bay; they were usually too late to make a serious attempt at whaling on the "east side" grounds. Rather, they would proceed along the coast until they met the "middle pack". If they managed to find a way through this "Death Trap" (Savours, 1960:130) and attained Cape York or

TABLE 7. Catch of bowhead whales by the *Arctic* of Dundee in Davis Strait and Baffin Bay during 1873 (from Markham, 1875:279). Markham (1875:255) described the *Arctic*'s cargo of oil as "the largest...ever gone home from Baffin's Bay."

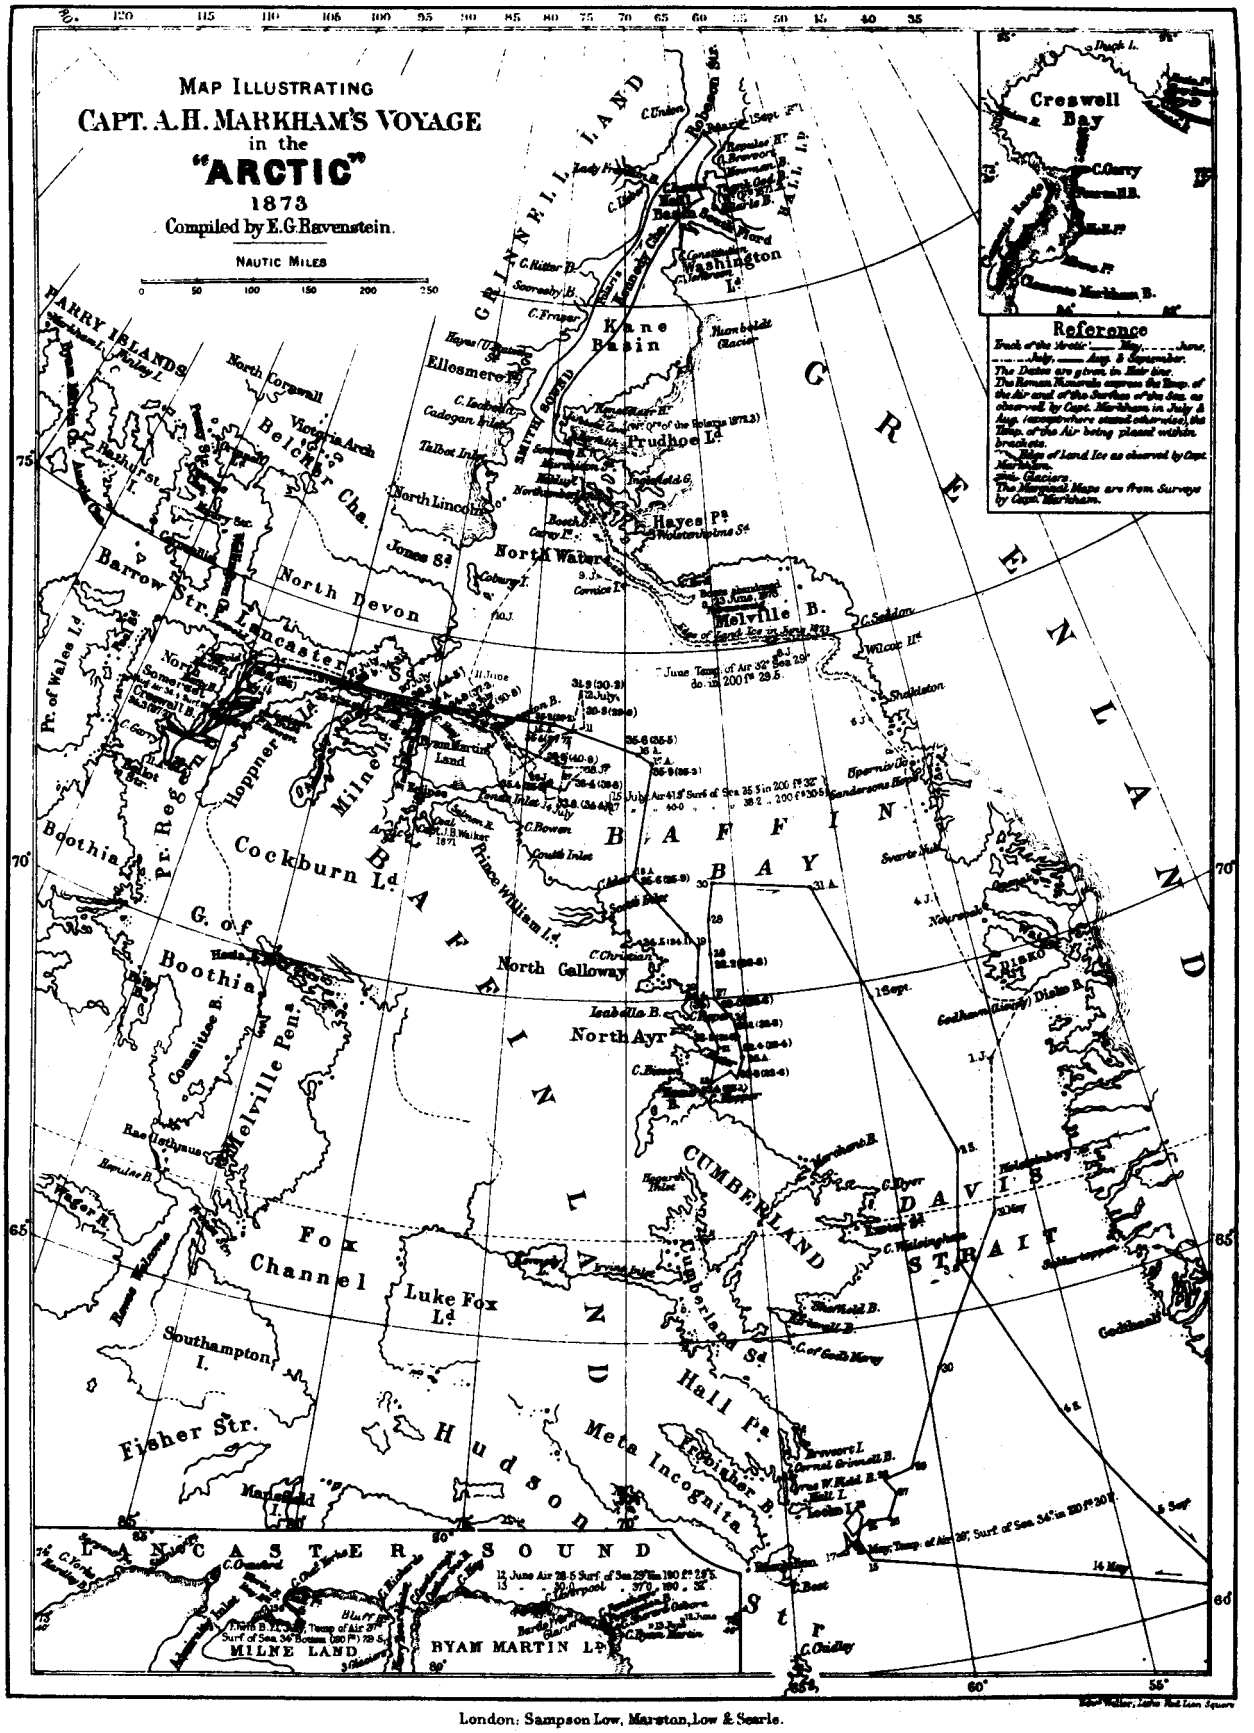

FIG. 6. Cruise track of the *Arctic* of Dundee during the 1873 season in Davis Strait and Baffin Bay (from Markham, 1875).

Cape Dudley Digges, they would usually be able to navigate through the "north water" and reach the Lancaster Sound region in June or July (e.g. Blake, 1874:79-80).

Between the "south-west fishing" and the "west water" of Lancaster Sound and Pond Inlet, the whalers did not expect to encounter many bowheads (Duncan, 1827:10-13; Southwell, 1898). However, some did see whales during the passage (e.g. Parry, 1821:9).

"West Water"

The *Arctic* reached the "north water" off Cape York on 9 June (Markham, 1875), which would be about a month early according to Lubbock (1937:279). From there she proceeded toward the mouth of Lancaster Sound. The fleet was working along the floe edge off Bylot Island and the mouth of Pond Inlet, the first whale being taken in the "west water" on 13 June.

While waiting for a passage up Lancaster Sound, the *Arctic* continued to work along the Bylot Island floe edge between Cape Byam Martin and Cape Graham Moore. The whales, according to one whaling captain, rarely appeared in Pond Inlet until 7 July, after which the inlet was "usually alive with fish" (Smith, 1922:39). Southwell (1898:407), however, maintained that the whales usually arrived in Eclipse Sound about 15 June (see Smith, 1922:34). Finally, on 27 June the *Arctic* reached Cape Hay and proceeded up the sound.

For most of the month of July, she cruised in Lancaster Sound and Prince Regent Inlet, finding whales to be abundant (Fisher, 1821:58 *et seq*; Gray, 1888; Lubbock, 1937:254, 399,422). (In 1868 the *Arctic* had taken 40 small bowheads in Prince Regent Inlet — Lubbock, 1937:393.) For a brief period in the middle of the month she returned to "our old fishing ground" off the mouth of Pond Inlet, where many large whales were present (see Smith, 1922:41-42). Low (1906:258) called this the place "where the principal summer catch is made." Brown (1868:544) stated that bowheads "accumulate in greatest numbers in the neighbourhood of Pond's Bay, and even up Eclipse Sound .... The Whales continue 'running' here until the end of June, and remain until about the end of August or beginning of September. The whalers think that if they can reach Pond's Bay by the beginning of August they are sure of a 'full' ship" (also see Goodsir, 1850:75,85). Admiralty Inlet sometimes had large numbers of whales in late July (Lubbock, 1937:399-400; Hall, 1876:207).

On the first of August the *Arctic* attempted to reach the Gulf of Boothia by way of Prince Regent Inlet, but ice conditions turned her back. All the whales in Prince Regent Inlet were said to be "heading in that direction [i.e. toward the Gulf of Boothia]" (Markham, 1875: 227). Several other authors wrote of the abundance of bowheads in Prince Regent Inlet and the northern Gulf of Boothia during July, August, and early September (Parry, 1826:94,160-161; Hall, 1970:131; Ross, 1835:119, 123-126,140-146,660; Low, 1906:56).

After taking her 28th whale off Cape Garry on 11 August, the *Arctic* returned directly to Scotland with "the largest cargo of oil that has ever gone home from Baffin's Bay" (Markham, 1875:255).

The *Arctic*'s early departure from the grounds must not be taken to mean that bowheads had disappeared from the Lancaster Sound region by mid-August. Parry (1826:36-37) apparently found them still numerous in many parts of the sound through the entire month of September, although the rapid formation of young ice would have driven out most of the whalers well before the beginning of October. Gray (1888) stated that the southward migration did not usually begin until late September, "on the formation of young ice in the sounds."

"Land-Floe Across"

Gray (1939) regarded certain years as "disastrous ... for the Davis Straits whales." These occurred when the land-floe persisted on the west side of Baffin Bay, blocking the entrances to Pond Inlet and Lancaster Sound ("the gate where the whales have to pass through" — Fairweather and Fairweather, 1928:24) until the arrival of the whaling fleet. The whalemen referred to this circumstance as a "land-floe across" (Gray, 1888). (Incidentally, 1873, the year of Markham's [1875] voyage, was not one of these "close seasons.")

Accounts by Sutherland (1852:V.2:324), Lindsay (1911), Lubbock (1937), and others testify to the large concentrations of bowheads that could assemble along the land-floe when their westward passage was obstructed. It was in such a "close season", 1823, that the *Dexterity* killed 20 whales "in a fall", i.e. in one lowering of her boats (Gray, 1939). On 14 July of that year there were no less than 41 sail made fast to the land-floe about eight miles north of Pond Inlet. Only one of these vessels was "clean" (without a catch), most having already caught from 8 to 14 whales. A similar situation existed in 1862, when the *Polynia* took 13 whales in less than two weeks (Barron, 1970:151).

"Rock-Nosing"

Although Markham's (1875) account may typify a successful season in the Lancaster Sound region, it gives no information about a third important segment of the British Davis Strait fishery: "rock-nosing". Those vessels that failed to fill their holds at the "south-west fishing" and the "west water" or "north water" of the Pond Inlet/Lancaster Sound region frequently headed for the fall fishing grounds inshore along the east coast of Baffin Island, also sometimes referred to as the "west water" or the "south-west fishing" (Lindsay, 1911: 203; Osborn, 1865:79), not to be confused with the Pond Inlet/Lancaster Sound whaling and the spring whaling off Resolution Island, respectively.

Toward the end of August or in early September the vessels generally would end their cruising along or "hooking onto" the floe-edge in Lancaster Sound and its adjoining inlets and fiords. While "rock-nosing", the vessels "lay at anchor in some harbor, and every morning the boats rowed out and watched for whales. It was cold, dreary work and very unpopular with the men; but whales late in the season were often large and well worth looking for" (Lindsay, 1911:203; also see Barron, 1895:13; Savours, 1960; Brown, 1868:544; *Eclipse*, 1906).

The whales were found "along the western edge of the 'mid-

dle pack'" at this season (Low, 1906:258; and see Smith, 1922:70). Virtually the entire Baffin coast between Cape Macculloch and Cape Dyer was used for "rock-nosing" (Savours, 1960:135; Lubbock, 1937; Lindsay, 1911:210 *et seq*; Goodsir, 1850:117). Barron (1970:194) claimed "it is singular that no whales have ever been captured off this Cape [Walsingham], or in the vicinity, " although he admitted they could be "plentiful" in Exeter Sound late in the year (1970:191).

Most of the vessels left for home between the first and the 20th of October (Brown, 1868:545; Gray, 1888), but some captains extended the season into early November, by which time their crews would usually be "rock-nosing" in Cumberland Sound (Savours, 1960) or along the Hall Peninsula between Cumberland Sound and Frobisher Bay (Barron, 1970:89).

"Rock-nosing" could begin from the south as well as the north. Vessels that failed to clear the "middle pack" often retreated along the Greenland coast and worked their way across Davis Strait at a lower latitude, making their first landfall at Cape Walsingham or Cape Searle, then proceeding northward along the East Baffin coast (Barron, 1970). The *Abram* (1839), for example, reached Baffin Island by the first week of August and took her first whale (11 ft 3 in. bone) off Cape Hooper on 4 August. From then until mid-September the vessel continued "rock-nosing" in company with several other vessels between Home Bay and Cape Searle. She set sail for home on 15 September.

In Figure 7 we have attempted to identify many of the harbors and headlands considered to be important refuges or landmarks by the "rock-nosers". Agnes' Monument, just north of Clyde River, was "a noted place for whales" (Barron, 1970:96), as were Cape Kater (Barron, 1970:138), Brodie Bay (Anon., 1836:6), and Home Bay (Barron, 1970:12,140). "Many heavy whales" were taken in late summer between Cape Kater and Home Bay as well (Barron, 1970:186).

Cumberland Sound

Although a large bowhead had been seen by John Davis when he discovered Cumberland Sound in July 1587 (Markham, 1889:61), the sound's commercial whaling potential was long overlooked. It was not until the later years of the Eastern Arctic fishery (i.e. after about 1840) that Cumberland Sound (also called Hogarth Sound and Northumberland Inlet; Kumlien, 1879:11) became recognized as a profitable whaling ground. William Penny did not find the abundance of whales he expected when he entered the sound in 1840 (Holland, 1970), but he was assured by the natives that the animals had been very numerous before his arrival (on 2 August) and that they would return "when the sun becomes low" (Tillotson, 1869:283). Cumberland Sound soon grew to be a popular area for early- and late-season whaling.

Low (1906:257) stated: "In March they [bowheads] are found along the edge of the land-floe of Cumberland gulf and Frobisher bay, where they remain until the beginning of May, when they cross to the Greenland coast." Natives of the sound claimed to see large numbers of bowheads at "the edge of the ice-floe" when they traveled long distances over ice to hunt

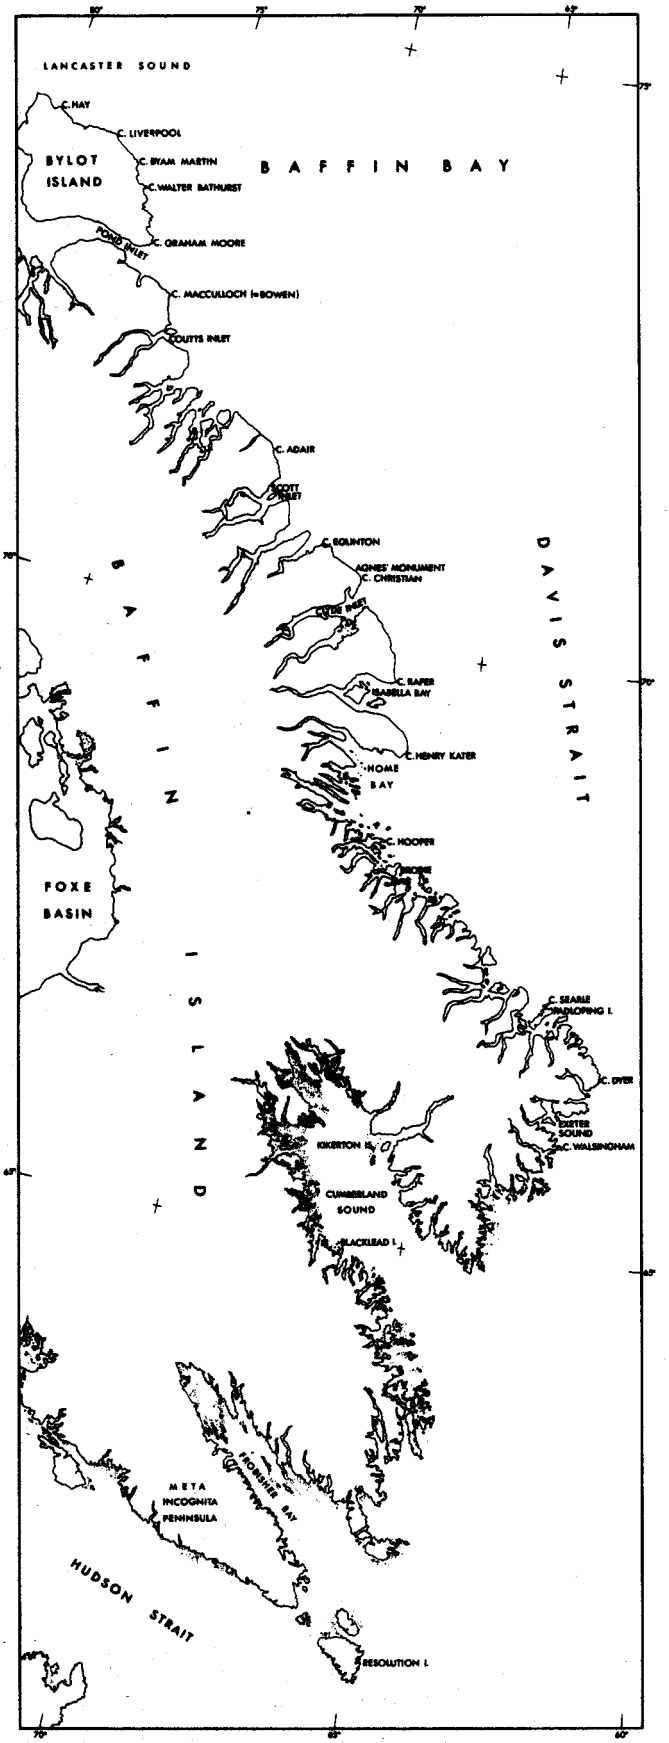

FIG. 7. The "rock-nosing" grounds along the east coast of Baffin Island, used principally for late-season (autumn) whaling. "Brodie" is Brodie Bay.

young seals early in the spring (Brown, 1868:545). American and Peterhead whalers in particular overwintered in Cumberland Sound (and occasionally Frobisher Bay; see Buddington *in* Clark, 1887:96) with the intention of gaining access to the "spring run of fish" (Lubbock, 1937:356-358; Faulkner, 1878; Buddington *in* Clark, 1887:95-96; Gray, 1888). Large catches could be made if the whalemen were on hand for "the first movement of the ice"; the brig *Georgiana* took 12 whales in two days here in 1853 (Buddington *in* Clark, 1887:96). The floe-edge was sometimes still 12-14 miles from land when the whalers began their early-season whaling activities (Barron, 1970:37).

"In October the whales again enter Cumberland gulf, and remain along the edge of the newly-formed land ice until December, when their position is unknown until their return in the following March" (Low, 1906:258). The *Hannibal* found bowheads "very numerous" in Cumberland Sound during late October 1859 (*WSL* 17(38):29 XI 1859; also see Barron, 1970:98,101,107; Lubbock, 1937:458-459). Bowheads had left the sound by 9 November — "a little later than sometimes they do" — when Faulkner (1878:176) overwintered there. On the other hand, Brown (1868:545) claimed the whales stayed in the sound until January, when freeze-up is complete (also see Howgate, 1879:37-43; Barron, 1970:194; Holland, 1970:32). Bowheads were also occasionally taken late in the season in Frobisher Bay (Wakeham, 1898:59).

The *Perseverance* (1877-1878) sailed from Peterhead on 19 July 1877 for Cumberland Sound. After reaching Blacklead Island on 18 August she proceeded up the sound to try the white whale driving at Kingwa (Clearwater) Fiord (see Mitchell and Reeves, 1981). She headed back down the sound at the end of August and began searching for bowheads, the first of which was seen on 27 October. Whales were then seen nearly every day until 9 November, when the hunt was terminated and the whalemen retired to winter quarters.

The following spring the crew of the *Perseverance* sighted their first bowhead on 7 April off Blacklead Island. The vessel (along with the *Alert* and *Polar Star*) cruised between Blacklead and Kikerton islands and around Wareham Island until mid-June, frequently sighting and lowering for bowheads.

Wintering Grounds

The one season for which the British and American whalers had little information on the bowheads' whereabouts was winter. Foul weather, ice, and long periods of darkness made whaling almost impossible. Forced overwintering by the whalers occurred from time to time and resulted in winter observations of bowheads. We have listed some records in Table 8.

In addition to the well-documented wintering grounds along the coast of western Greenland, it appears that bowheads winter along the line of moving pack ice from the mouth of Hudson Strait to the coast of Greenland. The mean maximum southern limit of the ice edge in winter (January-March) is from about 65°N latitude on the Greenland coast to 180 miles off Resolution Island (Markham, 1981:7). Southwell

TABLE 8. Sightings, kills and attempted kills of bowhead whales in winter (November-April) by overwintering nineteenth-century pelagic whalers or explorers

Date	Position	Remarks	Source
1 December 1821	In Foxe Channel, SE of SE extremity of Lyon Inlet	One whale seen	Lyon, 1824:96.
22 January 1822	In Foxe Channel, S of SE extremity of Lyon Inlet	One whale seen	Lyon, 1824:108.
1 February 1827	In holes of open water; between ca. 60 mi NW of Disco Island and 68°37′N, ca. 63°W	"Several" whales seen	Duncan, 1827:85; Lubbock, 1937:266.
2 February 1827	Between 69°13′N and 68°43′N; ca. 50 mi off west coast of Greenland	One whale killed; 9 ft 4 in. bone	"
7-8 February 1827	Among "bay ice"; ca. 68-69°N, off west coast of Greenland	"Several" whales seen	Duncan, 1827:87.
15-16 February 1827	Holes of water in ice; 68°58′N off west coast of Greenland	"Several" whales seen	Duncan, 1827:89-90.
17 February 1827	Ca. 69°N, ca. 60 mi NW of west coast of Greenland	3-4 whales seen; one struck but lost; one killed, 8 ft 1 in. bone	Duncan, 1827:90; Lubbock, 1937:267.
21 February 1827	Ca. 69°N, 63°W	"Several" whales seen	Duncan, 1827:91.
11-16 March 1827	Between 67°24′N and 67°34′N; in lanes of water among "bay ice"; well off the land, but longitude uncertain; apparently closer to Baffin than Greenland coast	Whales seen	Duncan, 1827:104-105; Lubbock, 1937:268.
25-27 March 1827	Ca. 61°30′N, 61°W; "South-west fishing"	Several whales seen and chased	Duncan, 1827:109-110.
25 April 1827	61°37′N, 61°W	One whale seen	Duncan, 1827:109.
27 April 1827	In "south-west fishery", ca. 61°N, 61°W	Whales chased	Duncan, 1827:110.
11-13 Nov. 1835	In heavy pack ice "southward of Cape Searle"	"A great many" whales seen	Lubbock, 1937:309-310.
27 Dec. 1835	62°57′N, in heavy ice near Resolution Island	A whale "heard"	Lubbock, 1937:317.
5 Jan. 1836	Within sight of Button Islands and Cape Chidley	Several whales seen	Lubbock, 1937:318.
11 Jan. 1836	60°N, off Labrador	Whales heard "frequently"	Lubbock, 1937:320.
28-29 Jan. 1836	Ca. 57-58°N, off Labrador	Three whales seen	Lubbock, 1937:323.
February, sometime in 1850s	Near entrance of Cumberland Sound	Two whales caught; "there were great numbers about"; weather "unusually mild".	Lubbock, 1937:363.
March or April 1951	Broken pack ice between 71°55′N, 66°55′W and 70°44′N, 63°44′W	One whale seen	Kane, 1854:390.
25 April 1851	Near 69°47′N, 63°W, off Henry Kater Peninsula, SE Baffin Island	One whale seen	Kane, 1854:357.
February 1855/56	Near Godhavn	Two captured; "great numbers" seen	Barron, 1970:70; Lubbock, 1937:363.
9 March 1858	Heavy pack ice ca. 90 mi west of Disko Island; ca. 69-70°N, 58-59°W	"Black whale" seen	M'Clintock 1860:85.
6 April 1858	67°18′N, in heavy pack ice of Davis Strait; within sight of Cape Dyer; ca. 58°W	Two whales seen	M'Clintock 1860:89.
Winter 1860/61 and 1861/62	Frobisher Bay, at the "edge of the ice"	"Several" whales captured	Clark, 1887:96.
27 December 1866, 4 and 9 January 1867	Off Marble Island (62°40′N)	"Several black whales" seen	Ross, 1974:92.
8 March 1867	Off Button Islands, mouth of Hudson Strait, in "South-West pack"	One large whale seen	Smith, 1922:220.
5 December 1872	Repulse Bay (66°15′N)	Two whales seen	Ross, 1974:92.
22 March 1914	Off Marble Island (62°40′N)	Bowhead sighting	"
"Depth of winter"	Off "Mansfield" (=Mansel) Island and other "more southern" islands on east side of Hudson Bay	Whales reportedly seen	Low, 1906:257.
13 April, year not stated	Depot Island - Fullerton area, NW Hudson Bay (63°50′N)	Bowhead sighting	Ross, 1974:91, Table 3.

(1898:407) was probably correct in asserting that the "southwest fishing" grounds east of Resolution Island were "doubtless the starting-place of the most southerly contingent of the migrating army of whales in Davis Strait."

There are areas of partially or well dispersed pack ice where some open water is consistently present in Smith Sound (the "North Water"), at both ends of Jones Sound, and in Frobisher Bay (Dey, 1981; Markham, 1981). "Recurring polynyas" have also been identified in Cumberland Sound, Bellot Strait, Committee Bay, and at the mouths of Lancaster Sound and Pond Inlet (Smith and Rigby, 1981; Stirling, 1981). In addition, intermittent leads occur along the coasts of Lancaster Sound, Prince Regent Inlet, and Cumberland Sound. It is possible that some bowheads winter in or near these areas. However, aerial surveys of the North Water, "the largest polynya in Canada and perhaps in the world" (Dunbar, 1981), in March-April 1978 and March 1979 failed to detect bowheads, and it was assumed that none were present (Finley and Renaud, 1980). A sighting during March 1981 in a crack in 95-99% pack ice north of Cape Dyer demonstrates the ability of bowheads to survive in apparently unpromising winter ice conditions (McLaren and Davis, 1981).

Brown (1868:545) acknowledged the belief, held by some, that the bowhead "leaves Davis Strait about the month of November, and produces young in the St. Lawrence River, between Quebec and Camaroa [Kamouraska?], returning again in the spring to Davis Strait." However, he does not seem to have subscribed to this notion himself: "It thus appears that they winter (and produce their young) all along the broken water off the coast of the southern portions of Davis Strait, Hudson's Strait, and Labrador" (also see Southwell, 1898; Low, 1906:258). "The Eskimo from the southern part of [Cumberland] sound and along the coast from Nugumeute [S.E. Baffin Island] to Hudson's Straits report whales as found in those localities all winter" (Kumlien, 1879:65).

Haven (1773:19) reported that whales (presumably bowheads) remained at the mouth of Nachvak Fiord, Labrador, all winter. Eighteenth-century records of Labrador Eskimos support the hypothesis that bowheads migrate along the northeast coast of Labrador in winter (Taylor, 1974). Unfortunately, Taylor's tables of bowhead occurrences do not give the dates (other than year). In his text, Taylor indicates that the whales "did not appear off the Labrador coast until November" (*cf.* our Table 1), and the Eskimo hunt apparently ended in most years by mid-December due to freezing of the bays (Taylor, 1974:32). Judging by the primitive methods used to capture the whales and the fact that baleen was an important product of the hunt, we have no doubt that most of the large whales hunted by the Eskimos of northeastern Labrador were balaenids. We are strongly inclined to agree with Taylor's supposition that most of them were bowheads, but we cannot rule out the possibility that right whales (*Eubalaena glacialis*), humpback whales (*Megaptera novaeangliae*), and even gray whales (*Eschrichtius robustus*) were at least occasionally caught (Spiess, 1978; Mitchell and Mead, 1977; Brice-Bennett, 1980 MS). The fact that one New England whaler returning from Davis Strait in 1729 received a quantity of baleen "at least fourteen feet long" from the "Indians" at Davis Inlet, Labrador, demonstrates that at least some of the whales stranded or killed along the Labrador coast were bowheads (Gosling, 1910:321-322).

The "Grand Bay whale" of the Basques and the "river St. Lawrence whale" of the Nantucket whalemen almost certainly refer to the bowhead (see Eschricht and Reinhardt, 1866; True, 1904; Allen, 1908). Thus, it appears that the idea of the bowhead entering the Strait of Belle Isle (Grand Bay) and Gulf of St. Lawrence has some merit. Elaboration of the arguments for and against a winter migration into these areas is outside the scope of this paper. Nevertheless, we consider it a distinct possibility that the early Basque whalers and later the Yankee pelagic whalers caught bowheads, at least early and late in their whaling seasons, in or near the Strait of Belle Isle.

Hudson Bay and Foxe Basin

Hudson Bay and Foxe Basin experienced a comparatively brief period of whaling activity, 1860-1915 (Ross, 1974, 1975). Almost all of the whaling in the bay was done by Americans and Scots. Ross examined a sample of logbooks and journals, plotting catches and routes followed by the whalers to show areas of whale abundance. Most kills were made in Repulse Bay, in the area north of Chesterfield Inlet, and near Marble Island (Ross, 1975:40). Roes Welcome Sound was the center of whaling activity, though the grounds eventually included Bay of Gods Mercy, the mouth of Fisher Strait, Frozen Strait, Duke of York Bay, and Lyon Inlet. Ross (1974) estimated the whaling grounds to encompass an area of 59 570 km^2, where he considered bowheads to be abundant from mid-May to mid-September (Ross, 1975:59, Map 12).

Most vessels entered Hudson Bay through Hudson Strait in summer, arriving at the grounds in mid-August (Ross, 1975:44). For approximately a month they cruised for whales in "the Welcome." "Usually both whales and whalers tended to move northward during the summer as ice conditions improved in the northern reaches of Roes Welcome Sound" (Ross, 1975:45). Sometime in September the vessels went into winter harbor, where they remained until at least the following June and sometimes until August. Marble Island, Depot Island, Cape Fullerton, and Repulse Bay were the principal wintering sites. Spring floe-edge whaling from boats began in May and continued until the ships could be dislodged from their winter harbors and deployed for cruising. After a second, and longer, season of summer whaling, most vessels left Hudson Bay by way of Hudson Strait.

Low's (1906:257) opinion concerning the migration of bowheads into and out of Hudson Bay was based on information he received from whalers:

> The whales are known to enter Hudson strait early in the spring; they have been captured around Big island in April and May, and at the western end of the strait in the latter part of May. They then cross to the west side of the bay along the edge of the open water, being found in June and early July along the land-floe on both sides of the southern part of Roes Welcome. As the Welcome clears of ice they proceed north to Repulse bay, and, still

later, pass through Frozen strait into Fox channel. Late in the autumn they again pass through Hudson strait going eastward.

Ross (1974) could find little evidence of bowheads being seen or killed in Hudson Strait. On the inbound passage, the whalers generally kept to the Baffin (north) side of the strait until reaching Big Island, then either headed toward the gap between Nottingham and Digges islands or continued straight westward (Ross, 1975:40-41). They usually kept to the middle of the strait on their return (eastward) passage (Ross, 1975:55,58). The lack of observations — Ross (1974) found only 16 Hudson Strait bowhead encounters in 69 logbooks and journals — may or may not indicate a low level of migratory movement in the strait. Ross (1974) stated: "Either whales seldom occurred in Hudson Strait or they were present at times when ships were absent." References to sightings or kills in the strait are not really unusual, occurring as early as May and as late as early August (Lubbock, 1937:439,442; Ferguson, 1938:182; Bernier, 1910:313; Gordon, 1887; Low, 1906:272). Most navigation occurred between mid-July and mid-September, so it is possible that the whales usually cleared the strait in advance of the whalers in summer and after them in fall. Observations of bowheads swimming predominantly east off Cape Hopes Advance between 15 October and 23 November 1980 (Finley *et al.*, 1982) provide some evidence that the whalers did indeed leave Hudson Strait before many bowheads did. The poor success of the lone whaling station in the strait, at Spicer Island, and the apparent failure of Eskimos living on the shores of Hudson Strait to make large or consistent catches, however, add to the uncertainty about the bowhead's migration through Hudson Strait (Ross, 1974).

The only alternate route into and out of Hudson Bay/Foxe Basin would be through Fury and Hecla Strait, which Bernier (1909:41) believed, on the basis of conversations with local natives, "opens every year in the month of September". Chapel (1860, *in* Ross, 1974) suggested that bowheads from Lancaster Sound moved south through Prince Regent Inlet and the Gulf of Boothia and into Foxe Basin through Fury and Hecla Strait. This movement would, perhaps, account for the possibility that the Repulse Bay area "received a separate influx [of whales] from Foxe Basin by way of Frozen Strait and Hurd Channel" (Ross, 1974), at least in some years.

While searching for a Northwest Passage, Parry (1824:301) reported sightings of bowheads in early August at about 69°30'N latitude, off the eastern entrance of Fury and Hecla Strait. As Ross (1974) put it, these observations by Parry "stand alone during the 19th century." An obstacle to evaluating the possibility of a consistent migration through Fury and Hecla Strait and the possible significance of Foxe Basin to the Eastern Arctic bowhead population is the lack of exploration and whaling activity in these areas (e.g. Manning, 1943). Lyon Inlet, Gore Bay, and the Winter Island area, where Parry (1824:101,106,126) reported bowheads in September and October (even surfacing in "small pools" created by the vessel as it worked through newly forming sheet ice), constituted the northern limits of the Hudson Bay commercial whale fishery (Ross, 1974, 1975).

In addition to whales migrating into and out of Hudson Bay/Foxe Basin, some may remain there year-round. Low (1906:257) stated that "some whales are supposed to remain during the winter in the waters of Hudson Bay, as they have been reported by the Eskimos as being seen in the depth of winter off Mansfield [Mansel?] and some of the more southern islands of the east side of the bay." Ross (1974) provided additional evidence of bowheads wintering in the bay, using the persistent shore lead, but he concluded: "Whether these scattered sightings represent outliers of a large winter-resident whale stock in Hudson Bay, or simply a few individual stragglers cut off from the outmigrating herd by encroaching ice, is uncertain."

Although it was believed until the 1940s that central portions of Hudson Bay remain open in winter, this view has since been refuted (Hare and Montgomery, 1949; Danielson, 1971). There is a shore lead around the edges of the bay, between the shelf of land-fast ice and the main body of heavy ice covering most of the bay in winter (Stirling, 1981:Fig.1). This shore lead can vary in width from one or one and a half miles to 30 or 40 nautical miles (Hare and Montgomery, 1949), with an average width of about 5 miles (8 km) along the western side of the bay (Danielson, 1971). The northwestern section of the bay, where virtually all whaling activity took place, "has perhaps a higher percentage of open water than any other part of the Bay because of the strong currents from Foxe Basin and the upwelling along the coast" (Hare and Montgomery, 1949:164). There are said to be small shore leads in winter along the east coast of Southampton Island (Danielson, 1971:96), and Stirling (1981:Fig.1) mapped a "recurring polynya" covering much of Roes Welcome Sound, continuous with the shore lead system of western Hudson Bay.

There is a polynya in northwestern Foxe Basin kept open in winter mainly by tidal activity and wind (Markham, 1981:9; Dey, 1981), and intermittent leads form in winter east of Prince Charles Island (Markham, 1981:195). A shore lead system similar to that in Hudson Bay exists in Foxe Basin, and polynyas are formed in the basin by widening of the shore lead off the lee shores of islands (Smith and Rigby, 1981:Figs. 9a-d).

Hudson Strait does not freeze over completely in winter, although pack ice is sufficiently dense to forbid conventional forms of navigation (Forward, 1956; Dey, 1981). Intermittent leads develop along much of the north side of the strait during winter (Markham, 1981:195).

It is possible that some bowheads winter in the Hudson Bay shore lead and near Southampton Island, in the Foxe Basin shore lead and polynyas, and in the dense, shifting pack ice of Hudson Strait. We think it unlikely, however, that the entire summer population overwinters in the bay.

Population Segregation

The whalers frequently remarked on the size of whales caught on different grounds. "Whales of different ages keep a

good deal together: hence young Whales frequent the bays; the old ones roam in the vicinity of the 'middle ice' of Davis Strait, and afterwards come into the bays; and those killed early in the year at Pond's Bay are chiefly young animals. Hence the whaler uses the terms 'middle-icers,' 'rock-nosers,' and 'Pond's-Bay fish' to designate not a separate species or even variety, but to express a geographical fact and a zoological habit" (Brown, 1868:545).

The hypothesis of a migration southward from Lancaster Sound, through Prince Regent Inlet, Gulf of Boothia, Fury and Hecla Strait, and Foxe Basin, then eastward through Hudson Strait, had substantial support among the whalemen, as did the argument that this segment of the migration involved females and young whales almost exclusively (Southwell, 1898;Fig.5). Gray (1888) claimed that the young whales found in May at the Cumberland Sound floe-edge "have migrated south during the previous autumn amongst the archipelago of islands forming the west side into Fox Channel [Foxe Basin], thence by Hudson's Strait to the pack-ice off Resolution Island." As Ross (1974) stated, however, "in the matter of Hudson Strait and Foxe Basin migration the whalemen's evidence was speculative or indirect." We have attempted to use evidence from the literature to evaluate various hypotheses concerning age- and sex-related segregation in bowhead populations.

The statement by Eschricht and Reinhardt (1866:11) that they did not find the number of females caught along the western coast of Greenland to be "out of proportion" to the number of males is taken as evidence against segregation of the sexes on the east side of Davis Strait. It is puzzling that Southwell (1898:406), who admitted that his own knowledge of whale distribution and movement along the Greenland coast was based largely on the work of Eschricht and Reinhardt, claimed "old males" cross Davis Strait to the Disko Island area in spring while "female and immature whales" move north in heavy ice along the Baffin Island coast. Barron (1970:49) mentioned a cow and calf taken at Svartenhuk or off Umanak Fiord ("N.E. Bay") and on another occasion a small bowhead taken early in the season off Disko — "the smallest I had seen upon the east side, with the exception of those which had not left their mothers" (Barron, 1970:160). This suggests that females with calves were not unusual here but that small bowheads unaccompanied by adults may have been seen only exceptionally on the "east side".

The "south-west fishing" clearly involved large whales of both sexes (Tables 6 and 7). At the spring whaling along the floe-edge of Cumberland Sound, there was a high percentage of small whales (Buddington *in* Clark, 1887:95-96; Barron, 1895:40). Both young and old bowheads were present at Cumberland Sound in May "amongst the pack-ice in the offing, the younger whales being nearest the land-floe" (Gray, 1888).

Perhaps the strongest case for segregation of young bowheads from adult males and females pertains to the Pond Inlet area in early summer. Here "the young fish always precede the older ones on their journey up from the south" (Markham, 1875:128). Thus, the whales caught early in the season at the floe-edge off Bylot Island and the mouth of Pond Inlet were expected to be small (Table 7; Parry, 1821:29-30; Gray, 1929); the whalers called these small whales "Pond's-Bay fish" (Brown, 1868:545) or "nursery fish" (Lubbock, 1937:343). A high proportion of the whales taken in "close seasons" supposedly were "nursery fish" or females accompanied by "suckers" (Gray, 1939). Whalers regarded Lancaster Sound as "the general nursery of the young whales" (Anon., 1821:25). In spite of these claims, captains who refrained from lowering for small whales sometimes succeeded in taking a number of large ones at the "Pond's Bay fishing" (Barron, 1970:7; Lubbock, 1937:351). Of the 20 whales taken by the *Cumbrian* between 11 July and 17 August 1823, presumably along the land-floe off Pond Inlet, eight were females averaging 45 ft 3 in. in total length, and 12 were males averaging 43 ft 2 in. (Table 5).

Deep inside Lancaster Sound and in Barrow Strait, Prince Regent Inlet, Admiralty Inlet, and Navy Board Inlet, many small individuals and females accompanied by calves were seen (Table 7; Parry, 1826:89,161). The argument follows for a separate southward migration along the west coast of Baffin Island by these components of the population.

One reason for the whalemen's strong opinion about such a migration scheme was that so few females and young whales were found in the "middle ice" of Baffin Bay in late summer and fall and on the "rock-nosing" grounds along the East Baffin coast (Barron, 1970:37; Gray, 1888; Southwell, 1898; Table 5). In contrast to the spring season, the whales taken in Cumberland Sound in fall were usually large (Faulkner, 1878:171; Lubbock, 1937:378,382,459; Barron, 1970:163). The *Abram* (1839) took whales with 11 ft 3 in., 9 ft 11 in., 11 ft, 10 ft, 9 ft 2 in., and 9 ft 1 in. baleen while "rock-nosing". But off Cape Searle on 12 September a "sucking whale" with 3 ft "bone" and yielding only three tons of oil was taken — an exception to prove the rule.

In his study of logbooks and journals pertaining to the Hudson Bay fishery, Ross (1974, 1975) indicated that small whales and females as well as adult males were killed there, and we are unaware of substantial published evidence demonstrating that the population of bowheads in Hudson Bay/Foxe Basin is anything but fully integrated.

We have considered the remarks of Scoresby (1820, 1823) as they relate to the question of seasonal segregation, although his experience was mainly in the bowhead fishery east of Greenland: in May he expected to find "grown fish" at ca. 79°N along the ice edge and in marginal broken ice, and small whales "of different ages" at ca. 80°N in what he called "fields, and sometimes in bays of the ice" (1820:V.2:209). In June, large whales were found "in every variety of situation" between 75°N and 80°N; small whales, "farther to the south than in the spring, at floes, fields or even among loose ice, but most plentifully about fields or floes, at the border of the main western ice" between 78°N and 78°30'N. Few "small fish" were encountered in July and afterward. Throughout the whaling season — April through July — "a very large kind of mysticetus" was caught in open water at ca. 76°N. Scoresby (1823:292) thought it "worthy of observation" that four whales taken during the second half of August off Davy Sound

at ca. 72°N were all large males. "This fact intimates a separation of the sexes at this season of the year; as upon all other occasions, I have almost invariably found an indiscriminate mixture of males and females."

Scoresby (1820:V.2:211) stated the hypothesis that whales caught at different latitudes or seasons are "distinguished by a difference of age or manners, and in some instances, apparently by a difference of species or sub-species." He cited observed variation of body proportions, particularly the ratio of head length to body length, as evidence of systematic differences. Eschricht and Reinhardt (1866:25) and Gray (1936) argued that the variation reported by Scoresby was more likely an expression of age or sex differences rather than one of systematic separation. Guerin's (1845) "Rock-nose" whale, "a distinct variety, if not a distinct species," arose from reasoning similar to Scoresby's. The "Rock-nose" supposedly was found principally in the bays and inlets of Davis Strait, where "it frequently places the extremity of its head, or nose as the whalers call it, close to the shore, upon a rock" (Guerin, 1845). In Guerin's view the "true Mysticetus" was to be found well away from the coasts, usually in the "middle ice", and only came near land in the fall during its southward migration. As Brown (1868:544-545) argued, Guerin's description of the "Rock-nose" as anything other than a normal bowhead is unconvincing.

On present evidence, we are unable to develop a plausible model accounting for seasonal segregation by age or sex in any bowhead population. However, the lore of early whalemen summarized above, together with recent research in Alaska (e.g. Braham *et al.*, 1980b; Carroll and Smithhisler, 1980), indicates that there is at least short-term segregation, and migratory routes and timing may differ according to age, sex, and possibly reproductive condition. Whether there are also systematic differences between or even within presently recognized regional stocks of bowheads is less certain (Mitchell, 1977 MS; Braham *et al.*, 1980a; Jarrell, 1981), but such possibilities merit further study.

Stock Separation - Harpoons as Markers

Whatever the degree of mixing between the Davis Strait/Baffin Bay and Hudson Bay/Foxe Basin populations, there is likely to be little interchange between either of these

TABLE 9. Some harpoon recoveries considered to suggest interchange between different stocks of bowhead whales

Date of Recovery	Stocks Involved	Summary of Evidence	Our Evaluation	Source
1716	Spitsbergen-Bering Sea	Whale washed ashore on western Kamchatka bearing "a harpoon of European workmanship, marked with Roman letters."	Eschricht and Reinhardt, critical commentators, chose to overlook the informant's illiteracy and the lack of documentation. They accepted the validity of the record.	Scoresby, 1820:V.1:9; Eschricht and Reinhardt, 1866:47.
1787	Spitsbergen-Davis Strait	Whaling captain found bowhead drifting in Davis Strait bearing harpoon recognized as that of his brother; later he learned the harpoon "had been put into the whale near Spitzbergen only two days before."	Distance between Spitsbergen and Davis Strait (at least 2500 km by way of either Kennedy Channel or round Cape Farewell) is too far for a whale to swim and/or drift in two days. No explanation of how harpoon was identified.	Eschricht and Reinhardt, 1866:24.
1805	Spitsbergen-Davis Strait	Capt. Franks unsuccessfully harpooned whale in Davis Strait; "later in the same year" his son killed whale near Spitsbergen with "his father's harpoon still sticking in it."	No explanation of how harpoon was identified.	"
1805	Spitsbergen-Davis Strait	Capt. Sadler killed whale at Spitsbergen "in which the harpoon of an Esquimaux was fixed."	Harpoon could easily have come from Eskimo inhabitants of East Greenland (Gray, 1935).	"
1812	Spitsbergen-Bering Sea	Bone harpoon found in whale "met with" in Spitsbergen area; see following entry for Scoresby's attribution.	Harpoon could easily have been from Eskimos of East Greenland (Gray, 1935).	Scoresby, 1820:V.1:10-11.
1813	Spitsbergen-Bering Sea	Crude stone lance found in whale near Spitsbergen; attributed by Scoresby to "some tribe [of Eskimos] inhabiting the shores of the frozen ocean, on the northern face of the American Continent, yet unexplored."	Lance could easily have been from Eskimos of East Greenland (Gray, 1935).	"
Before 1820	Spitsbergen-Bering Sea	Stone lance, "fixed to a piece of bone," found in a whale near Spitsbergen; see preceding entry for Scoresby's attribution.	Lance could easily have been from Eskimos of East Greenland (Gray, 1935).	"
1866	Spitsbergen-Davis Strait	"Esquimaux" harpoon found in small whale killed at 80°N off East Greenland	Harpoon could easily have been from Eskimos of East Greenland (Gray, 1935).	Southwell, 1898:412.
1870	Davis Strait-Bering Sea	Harpoon found in whale killed off Point Barrow (Alaska), marked "A.G." Attributed to bark *Ansel Gibbs* of New Bedford which had been whaling "in Cumberland Inlet [= Sound] and its vicinity for some ten or eleven years previously."	Other vessels might have had these initials.	Clark, 1887:98-99.
1928	Bering Sea-Spitsbergen(?)	"American" harpoon found in whale stranded on New Siberian Islands.	Plausible, but not conclusive.	Tomilin, 1967:32.
?	Spitsbergen-Bering Sea	"...northeast of Korea, they take every year a great number of whales, in some of which are found harpoons (*or* striking-irons) of the French and Dutch, who practise the whale-fishery at the extremities of Europe."	Unsubstantiated.	Scoresby, 1820:V.1:9-10; Eschricht and Reinhardt, 1866:46-47.
?	Spitsbergen-Davis Strait	Whale struck near entrance of Scoresby Sound (East Greenland) by Wm. Scoresby, Sr.; killed "the next day near the entrance of Omenak fjord, on the west coast [of Greenland], with the harpoons freshly imbedded in its body."	Minimum distance from Scoresby Sound to Umanak Fiord is 3000 km, an impossible distance for a whale, particularly an injured whale, to swim in one day. No explanation of how harpoon was identified.	Brown, 1868:540.
?	Spitsbergen-Bering Sea	Dutch harpoon marked "W.B." found in whale captured in "the sea of Tartary"; said to belong to William Bastiaanz, Admiral of the Dutch Greenland fleet, "and had been struck into the whale in the Spitzbergen sea."	Apparently based entirely on hearsay.	Scoresby, 1820:V.1:8-9; Zorgdrager, 1723:187 as cited by Eschricht and Reinhardt, 1866:47.

populations and those found east of Greenland (Spitsbergen stock) and west of the Northwest Passage (Bering Sea stock). All populations appear to follow such separate migration routes and schedules that their geographic isolation is for the most part assured (Tomilin, 1957, 1967:32,35).

The whaling literature contains numerous references to the finding or killing of whales with harpoons in them, indicating previous encounters with whalers. Frequently such discoveries have been considered as evidence for stock interchange (Eschricht and Reinhardt, 1866:24) or as proof of favorite geographic speculations (Scoresby, 1820:V.1:8-12; Brown, 1868:540-541). We have listed some of these harpoon recoveries in Table 9, and as can be seen, very few of them withstand critical scrutiny.

After reviewing these instances, we conclude that as evidence none are incontrovertible and few are even plausible. Southwell (1898:414) stated: "should an interchange of Atlantic and Pacific whales take place it is much more likely to be by way of the 'Northwest Passage' than along the shores of Asia and Europe". However, the route along the north coast of Eurasia, potentially linking the Spitsbergen and Bering Sea stocks, seems to have produced at least as many plausible records.

Recent observations of bowheads or probable bowheads in the eastern North Atlantic (i.e. Spitsbergen stock) led Jonsgård (1981) to postulate that at least some are "stragglers" from other stock areas. In particular, he wrote that "in all probability two bowhead whales" seen off southeast Greenland at 61°05'N latitude in early August "may have moved from western to eastern North Atlantic waters, because it seems to be well documented that eastern bowheads in former times only moved as far south as about 65°N in the Denmark Strait." He failed to mention, however, that infrequency of the bowhead's occurrence south of 65°N along the west coast of Greenland, especially in summer, is similarly well documented (Eschricht and Reinhardt, 1866:5; Brown, 1868).

Site Fidelity

There is some evidence that individual bowheads return to the same localities at the same seasons in successive years. Southwell (1898:403) was told by Captain Gray that "whalers come to know strongly-marked individuals, and recognise them from time to time, thus showing that the whales follow the same line of migration for many successive seasons." On the whaling grounds east of Greenland a whale "with a distinct white mark across one side of its nose" supposedly was seen in 1856 and again three years later in the same place. Another "with a growth like a bee-hive on the left side of its tail" was reportedly seen in 1867 and killed "almost on the same spot" five years later. Gray claimed to have seen yet another bowhead, this one with a "large white splash on its back," in 1880 and every year subsequently through 1886. The "most remarkable" repeat encounter with a bowhead, according to Southwell (1898:411), occurred in Davis Strait when the *Terra Nova* killed a large whale bearing a harpoon marked with the name of the *Jean* of Bo'ness. Supposedly at least 37 years had elapsed between the implantation of the *Jean*'s harpoon and the capture of the whale by the *Terra Nova*. Another bowhead was caught in 1863 by the *Active* of Peterhead, bearing a harpoon marked "Pow & Fawcos, Newcastle, 1839" (Lubbock, 1937:381). Unfortunately, no details about the localities of the initial strikes and the final captures of these two whales are given, and these records tell us nothing about site fidelity or longevity of bowheads.

Records of the shore whaling operations at West Greenland demonstrate that "the same individuals have been observed to return annually to the same bays and fiords" (Eschricht and Reinhardt, 1866:9). A whale captured in Amertlok Fiord in early January 1817 "had frequently been hunted in the preceding year, being readily identified by the loss of a piece of its tail and the growth of a large excrescence from the injured place." Another whale taken near Godhavn in mid-May 1837 was carrying a harpoon that had been implanted by a harpooner at the Danish "factory" at Godhavn in late February 1833.

Although details were not provided, Conover, Orr, and Parsons (1979:4-17) claimed that a bowhead sighting off Hall Peninsula in September 1978 was "a resight of an animal observed and photographed in mid-September, 1977."

It is evident that bowheads, like other large baleen whales, are conservative in their migratory habits.

CONCLUSIONS

There is no reason to believe the bowhead's distribution and migratory behaviour in the Eastern Arctic have changed in a major way during historic times, despite the drastic reduction in population size (Eschricht and Reinhardt, 1866:4,14; Southwell, 1898; Mansfield, 1971). Some whales continue to winter at the ice edge off Godhavn (Dalager *in* Vibe, 1967:81; Kapel, 1979:211) and in open water and loose pack ice elsewhere off West Greenland (McLaren and Davis, 1981). Spring sightings have been reported in recent years from Godhavn to as far north as 75°N latitude off Cape York (Anon., 1981). Thus it appears that the old whaling grounds along the coast of West Greenland are still visited seasonally by a few bowheads.

There are recent reports of bowheads wintering in the unconsolidated pack ice of Davis Strait (Turl, 1977), off Cape Dyer (McLaren and Davis, 1981), at the mouth of Hudson Strait, and just outside Cumberland Sound (Table 4; Fig. 4). Lack of reports from the Labrador coast may partly be explained by the low level of observation effort there. A spring migration through Lancaster Sound still occurs (Greendale and Brousseau-Greendale, 1976), as does a fall migration along the northeast coast of Baffin Island (Koski and Davis, 1979; Davis and Koski, 1980). Summering grounds such as Prince Regent Inlet, Admiralty Inlet, Navy Board Inlet, and Barrow Strait are still occupied, at least sparsely, and a noteworthy sighting of 10-20 bowheads was made in Robson Channel (Smith Sound) in late July (Koski and Davis, 1979; Davis and Koski, 1980). Concentrations of bowheads observed during summer months near Southampton Island in northern Hudson

Bay, in Repulse Bay, and in northern Foxe Basin suggest that the Hudson Bay/Foxe Basin stock also persists in its traditional areas of summer occupancy.

We can summarize the knowledge of the bowhead's migration — historic and present — as follows:

In winter, bowheads are distributed from the northeast coast of Labrador to the Greenland coast between Sukkertoppen and Godhavn. Although some appear to winter at the mouth of Hudson Strait, it is uncertain whether any remain in Hudson Bay or Foxe Basin for the entire winter. Probably at least a few whales do, but we doubt there is enough open water to support the entire population. Some bowheads may occasionally reach as far south along the Labrador coast as the Strait of Belle Isle, but reputed bowhead specimens from the Strait of Belle Isle and the Gulf of St. Lawrence need confirmation.

In spring, bowheads follow the ice edge northward in Davis Strait; some probably enter Hudson Strait and move westward into Hudson Bay as ice conditions permit. During May and June they can be expected to appear between Disko Bay and Upernavik on the east side of Davis Strait and from Resolution Island to the mouth of Cumberland Sound on the west side. Most of the whales wintering off West Greenland probably cross Davis Strait at about 72°N latitude and reach the floe edge off Pond Inlet and Lancaster Sound sometime in June or July. The Pond Inlet and Lancaster Sound regions likely serve as a summer feeding ground for some bowheads and as migration corridors for others.

During summer, when a maximum of open water is available, bowheads probably become more widely distributed than at any other time of year. They enter many of the sounds and inlets of the High Arctic as well as food-rich areas of northwestern Hudson Bay and western Foxe Basin, especially Roes Welcome Sound and Repulse Bay. Some individuals probably remain near the pack ice of Baffin Bay and Davis Strait, off the northeast coast of Baffin Island, in summer. Some movement through Fury and Hecla Strait may occur, but this remains a moot issue.

The fall migration begins in September and continues through much of October. Some whales that summered in the High Arctic move southward along the east coast of Baffin Island, reaching Cumberland Sound where a major concentration occurs in late autumn. Others cross to the West Greenland coast and begin to reappear at Upernavik in late September and October. Some of the whales that entered Prince Regent Inlet in summer may proceed southward through Fury and Hecla Strait into Foxe Basin. At least some of the whales that summer in Hudson Bay and Foxe Basin probably move eastward through Hudson Strait in the fall (see Finley *et al.*, 1982).

Because of the bowhead's consistent association with ice edge and broken pack ice habitat, some variability in distribution may be expected from year to year as ice conditions change.

The persistent belief of whalers that different components of the population make separate migrations is difficult to evaluate. Calves and small whales apparently form a large segment of the concentration at the Pond Inlet floe edge in late spring. Also, the dearth of young whales and old females along the east coast of Baffin Island in the fall was mentioned often enough by whalers to make it appear to have substance. The argument for a circumnavigation of Baffin Island by females and calves cannot be refuted on present evidence, although it is unlikely that *all* females and calves follow this route.

The statement by Eschricht and Reinhardt (1866) that no sex or age class predominated in the Greenland shore-based catch suggests that a separate Greenland stock could simply share a common summering range with Canadian stocks, then return to the east side of Davis Strait for the winter and early spring. Arguments can be made for one, two, or three stocks in the Eastern Arctic, considering that there are two well defined summering areas — northwestern Hudson Bay/southwestern Foxe Basin and the Lancaster Sound/High Arctic region — and three less well defined wintering areas — the western coast of Greenland, the area from Cumberland Sound to at least the central eastern coast of Labrador (possibly to the Strait of Belle Isle), and Hudson Strait/Hudson Bay.

Unlike the Western Arctic and Spitsbergen/Greenland Sea, where morphological differences have been recognized and discussed (Eschricht and Reinhardt, 1861, 1866; Scammon, 1874; Mitchell, 1977 MS; Braham *et al.*, 1980b), variability in size, proportions, and appearance of bowheads in the Eastern Arctic has been ascribed to age- or sex-related differences (Brown, 1868; *contra* Guerin, 1854).

The nature of available data makes it difficult to assess bowhead abundance in the Eastern Arctic. However, we can state that nothing we have seen in published accounts or in the unpublished records examined for this study inspires confidence in the population's ability to recover from overexploitation. In the absence of evidence to the contrary, we believe the population in Davis Strait/Baffin Bay numbers only a few hundred and therefore that it is still at much less than 10% of initial (1825) size. The population found during summer in Hudson Bay/Foxe Basin, much smaller initially, is probably also at a small fraction of its earlier level of abundance. Lack of systematic assessment makes it impossible to say more about this population's status.

ACKNOWLEDGEMENTS

We thank K. Nesheim for indexing references, A. Evely for securing and verifying references, G. Horonowitsch for data checking, and G. Ferrand for drafting the charts. Financial support for this project initially came from the Department of Indian and Northern Affairs (Contracts No. OTT 78-111 to C. Brice-Bennett and No. OTT 78-118 to M. McLaughlin). It was completed with support from Parks Canada (Contract No. 81-162 to R. Reeves), Petro-Canada, and People's Trust for Endangered Species.

APPENDIX A

After this paper had already been submitted to press, the report of a parallel but independent study, based on extractions from manuscript whaling logbooks and journals, became available (Ross, W.G., and MacIver, A. 1982. Distribution of the kills of bowhead whales and other sea mammals by Davis Strait whalers 1829-1910. Unpublished report prepared for Arctic Pilot Project. iv + 75 p.). Ross and MacIver plotted 1024 bowhead kills in the Eastern Arctic, by decade (1820-1910) and by month (April-October). The pattern of distribution and migration suggested by their charts is essentially the same as we have outlined.

We find their interpretations of the material and their extrapolations difficult to evaluate because Ross and MacIver chose not to list the sources they consulted. "No particular advantage would be gained by listing these manuscript sources individually" (Ross and MacIver, 1982:71) — except that it is necessary to scholarly research.

APPENDIX B

Klinowska has undertaken this study, and has compiled a preliminary statement of some problems and literature (Klinowska, M. 1982 MS. Winter habits of the Bowhead Whale (*Balaena mysticetus*) in West Greenland from 1799 to 1836, in relation to catch and drift ice conditions. International Whaling Commission, Workshop on the Behaviour of Whales, Seattle, Washington, 19-23 April 1982. Paper SC/A82/BW 1, p. 1-10 typescript + Tables 1-6.)

Stock definition of belugas and narwhals in Nunavut

Définition des stocks de bélugas et narvals du Nunavut

P. R. Richard

Fisheries and Oceans Canada / Pêches et des Océans Canada
501 University Crescent / 501 Université Crescent
Winnipeg, MB
R3T 2N6

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

La présente série documente les fondements scientifiques des évaluations des ressources et des écosystèmes aquatiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Research documents are produced in the official language in which they are provided to the Secretariat.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Richard, P.R. 2010. Stock definition of belugas and narwhals in Nunavut. DFO Can. Sci. Advis. Sec. Res. Doc. 2010/022. iv + 14 p.

ABSTRACT

This document provides information relevant to the definition of stocks of belugas and narwhals in Nunavut in response to a request from the Nunavut Wildlife Management Board. There is good evidence of seasonal geographic segregation between Nunavut beluga stocks, and even year-round in many cases. There is also good evidence of genetic, contaminant and morphological differences between many of them. Evidence for narwhal segregation between stocks is largely from tracking data, although some genetic and contaminant also hints at some degree of geographical partitioning. For hunting communities that rely on a predictable seasonal occurrence of animals for their subsistence, reducing chances of local depletion by hunting multiple stocks as suggested by present information is an appropriate approach to co-management.

RÉSUMÉ

Ce document présente de l’information pertinente à la définition des stocks de bélugas et narvals du Nunavut, en réponse à une demande d’avis scientifique du Conseil de gestion des ressources fauniques du Nunavut. Il existe de bonnes sources d’information portant sur la ségrégation géographique saisonnière et, dans bien des cas, annuelle des stocks de bélugas du Nunavut. Des résultats probants sur leur génétique, leurs niveaux de contaminants et leur morphologie supportent aussi ces conclusions. Chez les narvals, ce sont largement des résultats de suivis télémétriques qui supportent les conclusions relatives à la ségrégation saisonnière des stocks. Il y a aussi des données sur leur génétique et leurs niveaux de contaminants qui suggèrent des différences dans la répartition géographique de certains stocks. Pour des communautés de chasseurs qui comptent sur une présence saisonnière prévisible de ces espèces, l‘approche de cogestion appropriée pour réduire des risques de surexploitation locale est de définir autant de stocks que sont suggérés par l’information disponible.

INTRODUCTION

The Nunavut Wildlife Management Board (NWMB), in its review of advice provided by Fisheries and Oceans Canada (DFO) Science on Total Allowable Harvest (TAH) for Nunavut beluga and narwhal stocks, has asked DFO to provide clarification on its rationale for providing science advice on the basis of known summering stock aggregations rather than at the population level. The NWMB also asked for clarification about various terms used (e.g., population, stock, sub-stock, management unit) and for an update on the current stock identity of belugas harvested by hunters from Iqaluit and Kimmirut.

DISCUSSION

POPULATION TERMS USED FOR PROVISION OF ADVICE

Stock is a concept used variously in fisheries assessment but it generally refers to a resource unit, a group of animals that are subject to hunting removals (Stewart 2008). That means the age and sex classes of a population or mixed populations that are the valued target of the hunt.

The biological definition of a population is a reproductively isolated group of animals (Waples 1991). A “population” can also be a “stock” (a group of animals of interest) if it is reproductively isolated from other stocks.

Factors such as demographic and life history variability, habitat patchiness, environmental change, genetic sub-structuring and adaptability may result in temporally or spatially structured populations (Cope and Punt 2009). It is possible to have localized depletions or extinctions if this is not considered when harvesting occurs. It is therefore important to choose the definition of stock to suit the management goal. Avoiding local depletion is one such goal, particularly for hunting communities that rely on a predictable seasonal occurrence of animals for their subsistence. It is also promotes the conservation of genetic diversity which may result from adaptation to local conditions.

The term “sub-stock” was used by the Scientific Working Group of the Joint Commission on Conservation and Management of Narwhal and Beluga (JCNB) and the North Atlantic Marine Mammal Commission (NAMMCO) in the context of subdividing the widely accepted “Baffin Bay Narwhal” stock (SWG-JCNB 2005). This term was introduced in a conceptual model that proposed to sub-divide the previously defined Baffin Bay narwhal “stock” into smaller management units, given there was evidence that that overall stock might be composed of seasonally spatially discrete populations, which had annual site-fidelity to their summering ranges.

This review refers only to management “stocks”, keeping in mind that some of these stocks may or may not be “populations” in the biological sense. Reference to “sub-stocks” in previous documents should be interpreted as meaning “stocks”.

APPROACHES USED FOR STOCK DEFINITION

Stock definition of beluga and narwhal populations in Nunavut was derived from various sources of information:

1) studies of the seasonal range of the species in Nunavut and adjacent waters by documenting local and written reports of their occurrence,
2) appearance and behavioural differences of animals from different areas of Nunavut and adjacent waters,
3) studies of genetic and contaminant differences of animals from different parts of Nunavut and adjacent waters, and
4) tracking animals, using satellite-linked transmitters, to estimate their seasonal range and delimit areas of aggregations.

The combination of these data has allowed DFO and partners to identify six beluga stocks and five narwhal stocks in Nunavut, as well as several others in Nunavik, Greenland or Alaska. These are considered provisional management stocks in the sense that any new information that may inform these conclusions would be taken into consideration to revise the list if needed.

The use of summering stocks as management units is considered precautionary. As mentioned above, it is possible to have localized depletions or extinctions if this is not considered when harvesting occurs (Cope and Punt 2009). By adopting as many stocks as are suggested by available information, even if that information is preliminary and based on small samples, co-managers reduce the risk of over-exploitation associated with considering smaller stocks to be part of a more numerous and wider-ranging stock, when in fact they are segregated for all or part of the year and have some annual site fidelity to specific areas. An example of the depletion of a local beluga stock is the Ungava Bay stock, which has been severely depleted, perhaps eradicated, by commercial whaling (Reeves and Mitchell 1989). The numbers of belugas using Ungava Bay in summer in the past few decades is not known precisely but is so low that few, if any, are seen during surveys (Finley *et al.* 1982; Smith and Hammill 1986; Kingsley 2000; Gosselin *et al.* 2009). As a result, summer hunting in Ungava Bay has been closed, with a few exceptions, since 2005 (DFO 2009).

STOCK DEFINITION OF NUNAVUT BELUGA STOCKS

Nunavut beluga stocks were identified by various authors over the years (Sergeant and Brodie 1969, Sergeant 1973, Finley *et al*. 1982; Richard *et al.* 1990) and their identity was based on the disjunct distribution of beluga summering aggregations. Evidence that belugas returned annually to the same aggregation areas (“site fidelity”) was obtained when nine of 14 individually-marked animals seen in the Nastapoka estuary (Eastern Hudson Bay) in the summer of 1983 were resighted there the following summer (Caron and Smith 1990). During the summer, known individuals were repeatedly seen returning to the Nastapoka estuary after offshore visits (Caron and Smith 1990). More evidence of beluga annual site fidelity came from genetic and contaminant research (Helbig *et al.* 1990; Brennin *et al.* 1997; Brown Gladden *et al.* 1997, 1999; de March *et al.* 2002; de March *et al.* 2004), which showed that animals of both sexes with specific mitochondrial DNA (mtDNA) types were found in certain summering areas but not in others and that the measure of genetic distance between samples of beluga from different summering areas indicated that there was little exchange of individuals between them. Belugas from the Mackenzie Delta, Somerset Island, Cumberland Sound, the Nelson River, and Eastern Hudson Bay were also tracked over the summer, autumn and winter seasons. Tracked individuals from each summering aggregations did not overlap in distribution in either summer

or winter (Richard *et al.* 2001a, b; Richard and Stewart 2009; Smith 2008; Hammill, pers. comm.) and in some cases, neither in autumn or spring.

Appendix I lists the information used for stock definition of Nunavut beluga stocks. In summary, there is strong evidence from genetic, contaminant and tracking data to support the definition of the stocks of belugas in Nunavut. Local knowledge was useful input to the understanding of the seasonal occurrence of belugas in Nunavut waters but provided weak inference on their stock delineation. These summer aggregations of belugas are therefore considered separate stocks for the provision of advice on Total Allowable Harvest.

POPULATION IDENTITY OF BELUGAS HARVESTED BY IQALUIT AND KIMMIRUT

The stock(s) harvested by hunters from Iqaluit is not know for certain but is thought to be the Western-Northern-Southern (WNS) Hudson Bay beluga stock (Fig.1). The Western part of this population is identified by COSEWIC as the Western Hudson Bay beluga population. This stock is large (mean estimate of ~63,000 animals) and winters in Hudson and Davis straits. Belugas found in Frobisher Bay and hunted by Iqaluit residents in summer are thought to be strays from this large main stock which summers in Hudson Bay along the Kivalliq, Manitoba and Ontario coasts. It is plausible that a large stock ranges more widely than smaller ones. Most belugas caught around Kimmirut are taken in the autumn when the WNS Hudson Bay stock has moved into Hudson Strait (Smith 2008). They are similar genetically to those hunted in summer in Western and Northern Hudson Bay (de March and Postma 2003) and differentiate from those hunted in the High Arctic, West Greenland and Cumberland Sound (de March *et al.* 2002, de March *et al.* 2004). Finally, no tagged belugas from Cumberland Sound or eastern Hudson Bay have moved into Frobisher Bay or adjacent to Kimmirut (Richard and Stewart 2009; Mike Hammill, DFO, unpublished data), while several tagged belugas from the WNS stock (Nelson River) have been tracked close to Kimmirut in autumn and winter (Smith 2008).

STOCK DEFINITION OF NUNAVUT NARWHALS

Two stocks of narwhals were previously identified in Nunavut waters: the High Arctic stock (later referred to as the Baffin Bay stock by the JCNB and the Eastern High Arctic-Baffin Bay population by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC)) and the Northern Hudson Bay stock (Strong 1988). There is some preliminary but equivocal evidence of genetic and contaminant differences that suggest the existence of more stocks of narwhals (de March *et al.* 2003; de March and Stern 2003) (Fig.2). The only stock of Nunavut narwhals which clearly differentiates by both methods from the other ones is the Northern Hudson Bay stock. There is also some tracking evidence of individual fidelity to summering areas between years and intra-year evidence that show that the individuals from different summering aggregations of narwhals do not mix during summer and, in the case of the Somerset stock, also not during autumn and winter. Figure 2 shows three stocks hypothesized by the JCNB, for which the only information is the occurrence of animals, either that they have been sighted in those areas (Parry Channel) or that they are hunted by Nunavut or Greenlandic hunters (Jones Sound, Smith Sound). Separate stocks were hypothesized for those areas given that, for other stocks, there is evidence of site fidelity and restricted geographic movements in summer (JCNB 2006) but there is no data to draw any clear statements on the distinctiveness of their range or genetic makeup.

Appendix II lists the information used for stock definition of Nunavut narwhals stocks. In summary, there is strong evidence from genetic, contaminant and tracking data to support the definition of the Northern Hudson Bay summering aggregation as a separate stock from other

narwhals in Nunavut. The evidence for defining other narwhal stocks is strongest from tracking data and weakest from genetics and contaminants. Although there are differences in the latter data, differences may be overshadowed by the fact that many landed animals are caught during seasons of migration, diluting differences between samples. Local knowledge was useful input to the understanding of the seasonal occurrence of narwhals in Nunavut waters but provided weak inference on their stock delineation. To reduce the chances of depletion of local stocks, the recommended precautionary approach is to also consider summer aggregations of narwhals as separate stocks for the provision of advice on Total Allowable Harvest.

Appendix I: Information pertaining to stock definition of Nunavut beluga stocks

Western-Northern-Southern Hudson Bay Beluga stock (Identified by COSEWIC as Western Hudson Bay Beluga population)	
A) Seasonal range and aggregations based on local knowledge and reports	Repulse Bay, Churchill, Winisk, York Factory and Fort Severn residents report beluga occupying their area from May to September. Aggregation areas are in the estuaries of the Seal, Churchill, and Nelson rivers.
B) Appearance and behaviour	Belugas from Churchill and Arviat are on average smaller than the ones in Cumberland Sound, West Greenland, Somerset Island (Baffin Bay stock) and the Beaufort Sea but not different from those in Eastern Hudson Bay.
C) Genetics and contaminants	Churchill, Arviat, and Repulse Bay belugas differentiate genetically from those of Eastern Hudson Bay. Differences in concentrations of heavy metals were found between regions of the Arctic.
D) Seasonal range and aggregations based on tracking	Animals instrumented in July in the Churchill and Nelson river estuaries, MB, remained there at least until late-August or September. Tagged Nelson River estuary belugas migrated along the Kivalliq coast or offshore of islands along the Nunavik coast. All belugas tagged in WNS Hudson Bay wintered in Hudson Strait.

Richard, DFO, unpubl. data.*
Eastern High Arctic - Baffin Bay Beluga stock	
A) Seasonal range and aggregations based on local knowledge and reports	Residents of Pond Inlet, Arctic Bay, Resolute Bay and Grise Fiord report spring movements west through Lancaster Sound, summer residence around Somerset Island and eastward return movement in the autumn. Belugas spend the winter in the North Water polynia of northern Baffin Bay.
B) Appearance and behaviour	Belugas from the High Arctic and west Greenland are on average larger than the ones in Hudson Bay.
C) Genetics and contaminants	Grise Fiord and West Greenland beluga mitochondrial DNA (mtDNA) samples differentiate genetically from those of Southeast Baffin Island. Differences in concentrations of heavy metals were found between regions of the Arctic.
D) Seasonal range and aggregations based on tracking	Animals tagged at the Cunningham Inlet and Elwin and Creswell bays were tracked into Peel Sound in late July – early August. They migrated east along the Devon Island coast in September and October. Many entered Jones Sound but wintered in the North Water polynia of northern Baffin Bay. A few moved to West Greenland for the winter. Two tagged belugas (one at Somerset Island in Aug.; on at Devon Island in Sept.) were resighted a year later near Somerset Island.

References	*A) Pers. comm. to author; Remnant and Thomas 1992; Stewart et al. 1995; B) Sergeant and Brodie 1969; Doidge 1990; Stewart 1994; Heide-Jørgensen and Teilmann 1994; C) de March et al. 2002; Wagemann et al. 1990; Rosenberg 2003; D) Smith and Martin 1994; Richard et al. 2001a; Heide-Jorgensen et al. 2003a; Orr et al. 1998.*
Cumberland Sound Beluga stock	
A) Seasonal range and aggregations based on local knowledge and reports	Residents of Pangnirtung report that belugas summer in and around Clearwater Fiord (Midlurialik) and range further into the west part of Cumberland Sound in autumn and spring. Belugas with distinct deformities have reportedly been seen for decades.
B) Appearance and behaviour	Pangnirtung hunters report that resident belugas are bigger in body size, have different maqtaq, and behave differently than other belugas sometimes found along the west coast of Cumberland Sound or at the flow edge in the spring.
C) Genetics and contaminants	Combined analysis of contaminants and genetics suggest that belugas hunted by Pangnirtung residents are not hunted in Iqaluit or Kimmirut. Differences in concentrations of heavy metals were found between regions of the Arctic.
D) Seasonal range and aggregations based on tracking	Belugas tagged near Clearwater Fiord followed similar patterns of seasonal movement to those described in (A). None left the Sound during the autumn. They wintered in a polynia at the northeast corner of the mouth of Cumberland Sound
References	*A) Pers. comm. to author; Kilabuk 1998 ; B) Pers. comm. to author; Kilabuk 1998; C) de March et al. 2004; Wagemann et al. 1990; Rosenberg 2003; D) Richard and Stewart 2009; P. Richard, DFO, unpubl. data.*
Eastern Beaufort Sea Beluga stock	
A) Seasonal range and aggregations based on local knowledge and reports	Kugluktuk hunters report occasional visits into Coronation Gulf from Dolphin and Union Strait by Eastern Beaufort Sea belugas.
B) Appearance and behaviour	
C) Genetics and contaminants	Eastern Beaufort Sea belugas show significant mtDNA genetic differences with belugas from Nunavut. Differences in concentrations of heavy metals were found between regions of the Arctic.
D) Seasonal range and aggregations based on tracking	Belugas of both sex tagged at the Mackenzie Delta in mid-July and early August, moved no further east than Amundsen Gulf or Viscount Melville Sound. In autumn, they migrated west into the Chukchi Sea, ending in the Bering Sea where they wintered.
References	*A) Lois Harwood, DFO Yellowknife, pers. comm.; C) Brown Gladden et al. 1997, 1999; Wagemann et al. 1990; Rosenberg 2003; D) Richard et al. 2001b; P. Richard, DFO, unpubl. Data.*

James Bay Beluga stock	
A) Seasonal range and aggregations based on local knowledge and reports	Belugas have been observed in James Bay in winter but they are seen by locals mainly in summer when they approach the coastline and enter river mouths.
B) Appearance and behaviour	
C) Genetics and contaminants	Preliminary results suggest that previously unknown genetic types occur in James Bay.
D) Seasonal range and aggregations based on tracking	Belugas tagged in summer in James Bay in both 2008 and 2009 have remained in the area well into December, showing no signs of migrating out of James Bay for the winter.
References	*A) Jonkel 1969; OMNR staff, pers. comm. to author; C) Lianne Postma, DFO, pers comm.; D) M. Hammill, DFO, pers. comm.*
Eastern Hudson Bay Beluga stock	
A) Seasonal range and aggregations based on local knowledge and reports	Nunavik hunters report that belugas in Hudson Strait in spring and early summer. Sanikiluaq hunters report that belugas usually arrive in late June, although some have occasionally been found in winter. In summer, hunters of both areas report that belugas are distributed throughout the Eastern Hudson Bay arc and around the Belcher Islands. Nunavik hunters observe belugas migrating east along the Nunavik Hudson Strait coast and into Ungava Bay in autumn.
B) Appearance and behaviour	Belugas from Eastern Hudson Bay are on average smaller than the ones in Cumberland Sound, West Greenland, Somerset Island (Baffin Bay stock) and the Beaufort Sea but not different from those in Western Hudson Bay.
C) Genetics and contaminants	Most belugas from Eastern Hudson Bay are differentiated genetically from belugas from all other stocks in Nunavut. They share genetic types with the St. Lawrence stock.
D) Seasonal range and aggregations based on tracking	Belugas tagged at the Little Whale and Nastapoka rivers remained in the Eastern Hudson Bay arc (including the Belcher Island waters) during summer. They migrated along the Nunavik coast to the Labrador Sea for the winter.

Appendix II: Information pertaining to stock definition of Nunavut narwhal stocks

Somerset Island Narwhal stock	
A) Seasonal range and aggregations based on local knowledge and reports	Resolute hunters report seasonal occurrence of narwhals in Barrow Strait, Peel Sound and Prince Regent Inlet between spring and fall.
B) Appearance and behaviour	
C) Genetics and contaminants	Creswell Bay narwhal samples were genetically different from Repulse Bay and Pangnirtung samples.
D) Seasonal range and aggregations based on tracking	Animals tagged at Creswell Bay migrated through Lancaster Sound in October and November to reach mid-Baffin Bay for winter. Two returned to their Somerset Island summering area the following year. A third was resighted migrating through Lancaster Sound five years later.
References	*A) Pers. comm. to author; Remnant and Thomas 1992; C) de March et al. 2003; de March and Stern 2003; D) Heide-Jørgensen et al. 2003b, 2008.*
Admiralty Inlet Narwhal stock	
A) Seasonal range and aggregations based on local knowledge and reports	Arctic Bay hunters report seasonal occurrence of narwhals in or near Admiralty Inlet from May to December.
B) Appearance and behaviour	Some hunters reported observing two forms of narwhals: a larger one and a smaller one.
C) Genetics and contaminants	Arctic Bay narwhal samples were genetically different from Igloolik, Qikiqtarjuaq and Pangnirtung samples.
D) Seasonal range and aggregations based on tracking	Narwhals tagged in Admiralty Inlet migrated along Baffin Island to Davis Strait where they wintered. One returned to the mouth of Admiralty Inlet the following spring.
References	*A) Pers. comm. to author; Stewart et al. 1995; B) Remnant and Thomas 1992); C) de March et al. 2003; de March and Stern 2003; D) Dietz et al. 2008;*
Eclipse Sound Narwhal stock	
A) Seasonal range and aggregations based on local knowledge and reports	Pond Inlet hunters report seasonal occurrence of narwhals in or near Eclipse Sound area from spring to fall
B) Appearance and behaviour	Some hunters report differences in shape and colour of some narwhal observed.
C) Genetics and contaminants	
D) Seasonal range and aggregations based on tracking	Narwhals tagged in the Eclipse Sound area migrated along Baffin Island to Davis Strait where they wintered.

East Baffin Island Narwhal stock	
A) Seasonal range and aggregations based on local knowledge and reports	Local hunters report seasonal occurrence of narwhals in East Baffin fiords and bays from spring to fall.
B) Appearance and behaviour	
C) Genetics and contaminants	Qikiqtarjuaq and Clyde River samples were genetically different from Repulse Bay, Arctic Bay, and Grise Fiord samples, and Qikiqtarjuaq samples from Pond Inlet samples. Contaminant differences were also found.
D) Seasonal range and aggregations based on tracking	N/A
References	*A) Pers. comm. to author; Remnant and Thomas 1992); B) Remnant and Thomas 1992; C) de March et al. 2003, de March and Stern 2003.*
Northern Hudson Bay Narwhal stock	
A) Seasonal range and aggregations based on local knowledge and reports	Local hunters report seasonal occurrence of narwhals in the Repulse Bay-Frozen Strait-Lyon Inlet area from spring to fall.
B) Appearance and behaviour	One hunter reported a larger darker form with a longer tusk than lighter-coloured narwhals but most hunters did not see noticeable differences.
C) Genetics and contaminants	Repulse Bay samples were genetically different from all the others. Contaminant samples were also different from narwhals from several other communities.
D) Seasonal range and aggregations based on tracking	Narwhals tagged in Lyon Inlet and Repulse Bay migrated through Foxe Channel and Hudson Strait in November and December to Davis Strait where they wintered. Two returned west through Hudson Strait the following spring.

Fall Movements of Belugas *(Delphinapterus leucas)* with Satellite-linked Transmitters in Lancaster Sound, Jones Sound, and Northern Baffin Bay

P.R. RICHARD,[1] M.P. HEIDE-JØRGENSEN[2] and D. ST. AUBIN[3]

(*Received 25 September 1996; accepted in revised form 7 October 1997*)

ABSTRACT. Six adult belugas, *Delphinapterus leucas*, (2 males, 4 females) were instrumented with satellite-linked transmitters in Croker Bay, southeastern Devon Island in the Canadian High Arctic in mid-September 1995. Some days, the animals remained close to shore along the southeastern and eastern shoreline of Devon Island, presumably foraging for arctic cod *(Boreogadus saida)* and other prey. They spent the rest of the time in the deep waters of Lady Ann Strait, eastern Jones Sound, and the waters southeast of Coburg Island, presumably feeding on deepwater prey. Only males went farther north in waters off southeastern Ellesmere Island. The belugas' swimming speeds decreased in the later part of the study period. Their last transmissions came from the North Water, an area where belugas are known to winter. Results of this study were not sufficient to determine the extent of movement of belugas between the eastern Canadian Arctic and Greenland.

Key words: beluga, *Delphinapterus leucas*, High Arctic, North Water, satellite telemetry, swimming speed, fall migration

RÉSUMÉ. À la mi-septembre 1995, on a installé des émetteurs en liaison avec un satellite sur six bélugas adultes (*Delphinapterus leucas*) — 2 mâles, 4 femelles — dans la baie Croker, au sud-est de l'île Devon dans l'Extrême-Arctique canadien. Certains jours, les six bélugas se tenaient près des côtes sud-est et est de l'île Devon, probablement à la recherche de saidas (*Boreogadus saida*) ou d'autres proies. Ils ont passé le reste du temps dans les eaux profondes du détroit de Lady Ann, de l'est du détroit de Jones, et dans les eaux du sud-est de l'île Coburg, se nourrissant probablement de proies habitant les grands fonds. Seuls les mâles se sont rendus plus au nord dans les eaux au large du sud-est de l'île Ellesmere. La vitesse de nage des bélugas a diminué durant la dernière portion de l'étude. Les derniers signaux provenaient de l'Eau du Nord, une région où l'on sait que les bélugas passent l'hiver. Les résultats de cette étude sont insuffisants pour évaluer l'ampleur des déplacements de bélugas entre l'est de l'Arctique canadien et le Groenland.

Mots clés: béluga, *Delphinapterus leucas*, Extrême-Arctique, télémesure par satellite, vitesse de nage, migration automnale

INTRODUCTION

Thousands of belugas *(Delphinapterus leucas)* spend July and August in the waters surrounding Somerset Island in the central Canadian Arctic (Koski and Davis, 1980; Smith and Martin, 1994). They later migrate eastward along the southern shore of Devon Island and north along its eastern shore during September (Fig. 1). Large numbers of belugas are also observed migrating south along the northwestern coast of Greenland, appearing first in the northernmost district (Avanersuaq) in September. Shortly after, in early October, they are usually seen farther south, in the district of Upernavik (Heide-Jørgensen, 1994). Some belugas are also known to winter in the North Water (northwest Baffin Bay and Smith Sound), but the large majority of Canadian Arctic belugas are thought to winter in West Greenland near Disko Bay (Doidge and Finley, 1993). The number of belugas wintering in West Greenland has declined in the last two decades (Heide-Jørgensen et al., 1993; Heide-Jørgensen and Reeves, 1996).

Belugas from Grise Fiord (Canadian High Arctic) and central West Greenland attain similar size at physical maturity (Heide-Jørgensen and Teilmann, 1994; Stewart, 1994). The absence of morphological differences, however, does not prove conclusively that the two samples belong to the same stock. Satellite tracking of the movements of individuals can offer direct evidence of beluga stock relationships. The movements of belugas during summer and the early part of their fall migration in Barrow Strait and Lancaster Sound have been described by Smith and Martin (1994), who attached satellite-linked tags to 23 belugas. However, they were unable to determine whether those belugas moved between Canadian and West Greenland waters because the transmitters, which had been attached to the whales in summer, ceased transmitting in early autumn.

This study was designed to test the hypothesis that animals tagged along the Devon Island coast in September would cross to Greenland and to gather data on their migration routes. Also, information on the horizontal and vertical movements of tagged belugas during the fall would contribute to our understanding of beluga ecology. Finally, beluga numbers are usually estimated by aerial surveys, which can count only animals at or near the surface. Because of the need to determine how many diving belugas may have been missed during surveys, measures of the proportion of time belugas spent near the surface and at depth would also help with the interpretation of survey results.

In this paper on six belugas tagged at Croker Bay, Devon Island, in September 1995, we give details of their movements, swimming speeds, and habitat use in relation to ice and depth over the following nine weeks. Other papers in this issue describe the dive activity of the same animals (Heide-Jørgensen et al., 1998) and the results of a winter aerial survey of the North Water beluga population (Richard et al., 1998).

MATERIALS AND METHODS

Study Area

The study area included Croker Bay, Devon Island, eastern Lancaster Sound, eastern Jones Sound, and northwestern Baffin Bay north to Smith Bay, southeastern Ellesmere Island (Fig. 1). The waters in these areas are largely over 200 m deep. A deep trough, with depths over 400 m, runs along the east coast of Devon Island and then north and west into Jones Sound, where depths of more than 800 m occur in some parts. Waters along southeastern Ellesmere Island and east and southeast of Coburg Island are somewhat shallower, varying between 100 and 400 m in depth. Ice conditions in late September vary from year to year. Median ice cover calculated between 1959 and 1974 is medium (2/10 to 5/10) for Jones Sound and open water for the rest of the study area (Markham, 1981). The median time at which ice cover reaches 9/10 (i.e., winter ice) over the whole area is mid-October. By 21 September 1995, most of the study area had between 6/10 and 9/10 ice cover, and by 5 October, most of the area had 9/10 ice cover, including considerable multiyear ice (Weekly Composite Ice Charts, Canadian Ice Service, Environment Canada, 1995).

Aerial reconnaissance along the southeastern Devon Island coast on 10 and 11 September 1995 revealed that belugas were abundant in Croker Bay (Fig. 1) and that ice and weather conditions were suitable for a live capture operation. Croker Bay, a fjord approximately 40 km long and 15 km wide, varies in depth from 100 m to 400 m at its centre. It is forked at the northern end and has two active glaciers calving icebergs. A camp was set at the southeastern corner of the bay (approx. 74˚33′N 82˚55′W).

Live-capture and Tagging Methods

From our capture camp, we observed belugas generally moving southeastward along the shore and out of the bay, in groups of one to several hundred. We captured six of those belugas (2 males, 4 females) between 12 and 16 September 1995 by immobilizing them along the shore using a 1.2 m diameter hoop with a 1.4 m pursing net. While we attempted to take animals from different pods, it is possible that some belonged to the same pod, since we observed tagged animals returning into the bay hours after being released. The four captured females were accompanied by large calves, presumed to be 1–3 years old because they were grey-coloured and approximately two-thirds to three-quarters the size of the adult females (Caron and Smith, 1990; Doidge, 1990).

Blood for hematological and plasma chemical analysis, skin samples for genetic analysis, and blubber for contaminant analysis were taken from each beluga. Each was then equipped with a satellite-linked time-depth recorder (SLTDR) or "tag" (Table 1), and identification bands (Orr and Hiatt-Saif, 1992) were put on both flippers. After a 40–55 minute handling period, the animals were released. The accompanying calves stayed around the capture site during these procedures and swam away with the females upon their release. On two occasions during the period we spent in Croker Bay, a tagged beluga was resighted in groups of belugas that included calves, its behaviour apparently unaffected by the live capture or the tag. This also indicates that the belugas' movements were not all southeasterly in direction, and that some pods reentered Croker Bay after having passed our camp.

The tags, model SDR-T6, were manufactured by Wildlife Computers Ltd. (Redmond, Washington). They contained a transmitter (model ST-6, Telonics, Mesa, Arizona), a pressure transducer, and a microprocessor, cast in epoxy. The transmitters were glued into a flexible rubber saddle (Ureol® polyurethane) 5 mm thick designed by the Greenland Institute of Natural Resources (Fig. 2). The transmitter housings measured 17.3 × 9.7 × 2.8 cm and the saddle-mounts 22 × 22 × 6 cm. The entire package weighed about 1 kg in air. The tags were attached to the belugas by three 8 mm polyethylene surgical pins (PEHD 1000) through the dorsal ridge. The animals showed no visible reaction to the surgical procedure. The saddles were secured to the pins and held in place with washers. The ends of the pins were melted to prevent the bolts from being torn off.

Each unit had a power output of 0.5 watts and was powered by four lithium C cells (3.5V), which were capable of 54 000 transmissions at 0˚C. None of the transmitters were set on a duty cycle, and the only battery-saving features were a daily maximum of 1000 transmissions and a saltwater switch, which prevented transmissions after the switch was wet for more than 0.1 s. The minimum time between transmissions was 45 s. Each transmission contained 8 to 12 bytes of data in addition to its identifier number. Following every 15 transmissions, a status message relayed information about the total number of transmissions and the voltage of batteries. Data from the

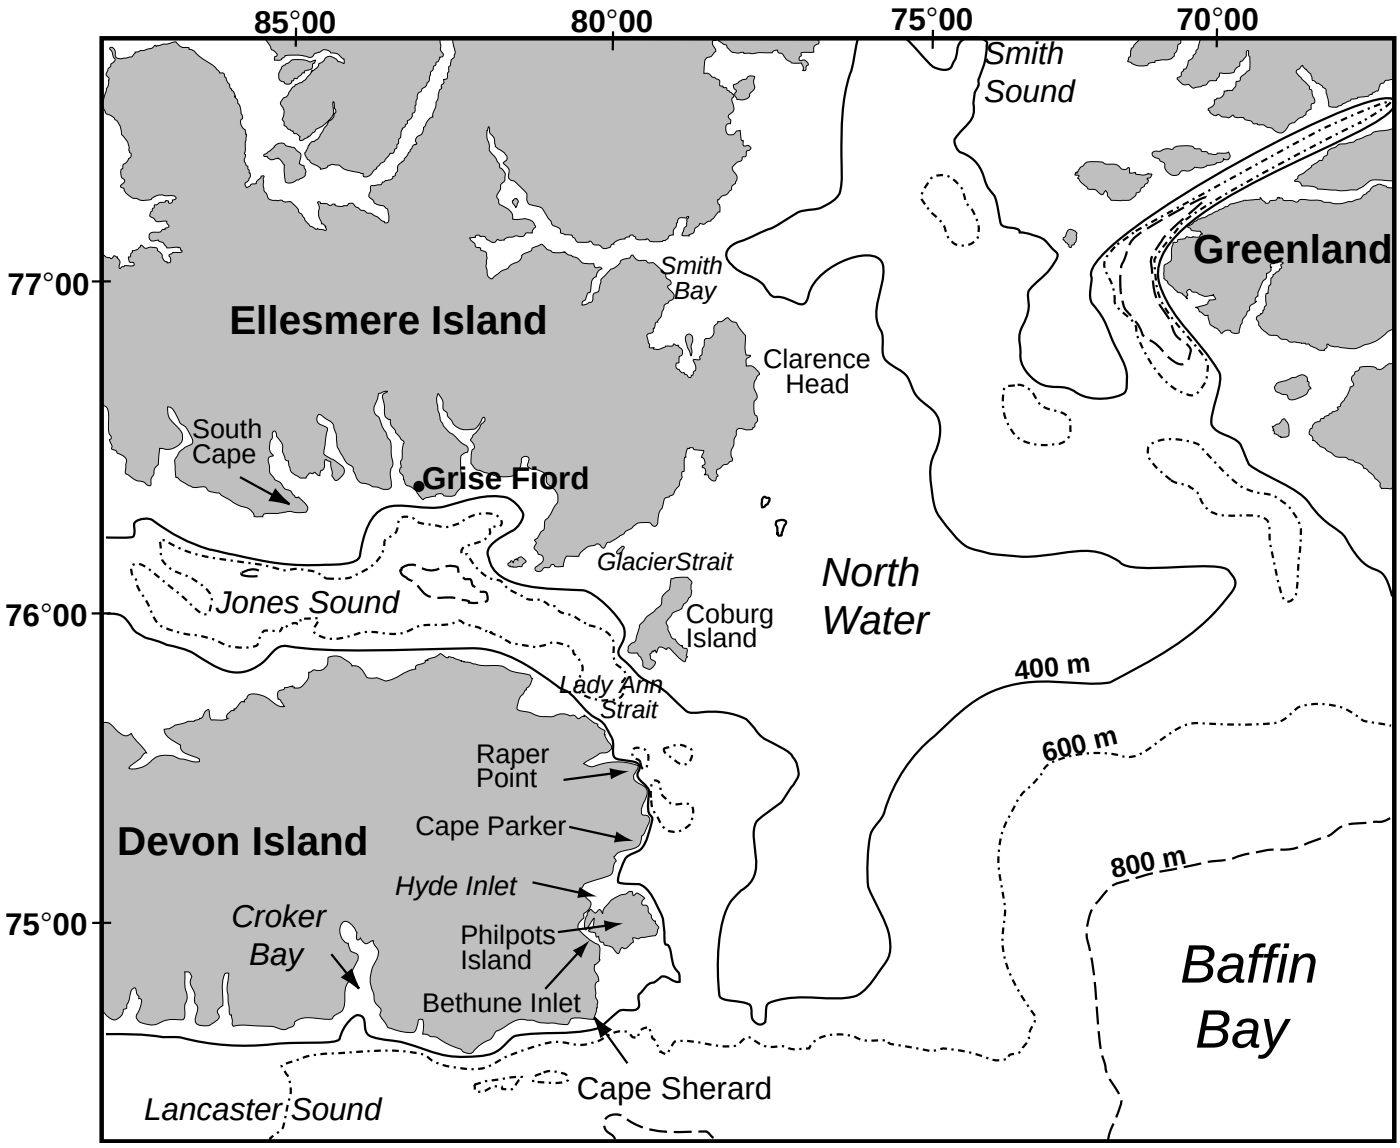

FIG. 1. Study area, with place names and bathymetric contours.

TABLE 1. Description of the belugas captured and duration of their tags' signals and locations. Quality locations (indices 1–3) are in error by 1 km or less.

Tag #	Sex	Length (cm)	Date of capture	Date of last location	Number of signals sent	Days till last signal	Days till last quality location
20688	M	465	14 Sept 95	16 Oct 95	18 350	37	33
20689	F	404	14 Sept 95	16 Oct 95	21 583	48	33
20690	F	368	12 Sept 95	17 Oct 95	21 200	37	34
20694	F	372	15 Sept 95	29 Oct 95	17 695	47	45
20695	F	392	16 Sept 95	4 Nov 95	26 089	52	50
20696	M	408	17 Sept 95	10 Nov 95	25 666	60	55

transmitters were received via the ARGOS Data Collection and Location System (DCLS) (ARGOS, 1988).

Analytical Methods

When sufficient numbers of signals were received during a satellite pass, the ARGOS DCLS estimated the position of the tag and assessed the quality of that estimate. We used only good-quality locations (quality indices of 1–3) with predicted errors less than or equal to 1 km. Location and movement tracks were plotted on polar azimuthal base maps. Distances were calculated using great circle arcs on a spherical model of the globe 6371.11 km in diameter (Maling, 1989, 1993).

Swimming speed was estimated using the great circle distance and the elapsed time between consecutive locations. Two sources of bias affect the estimation of swimming

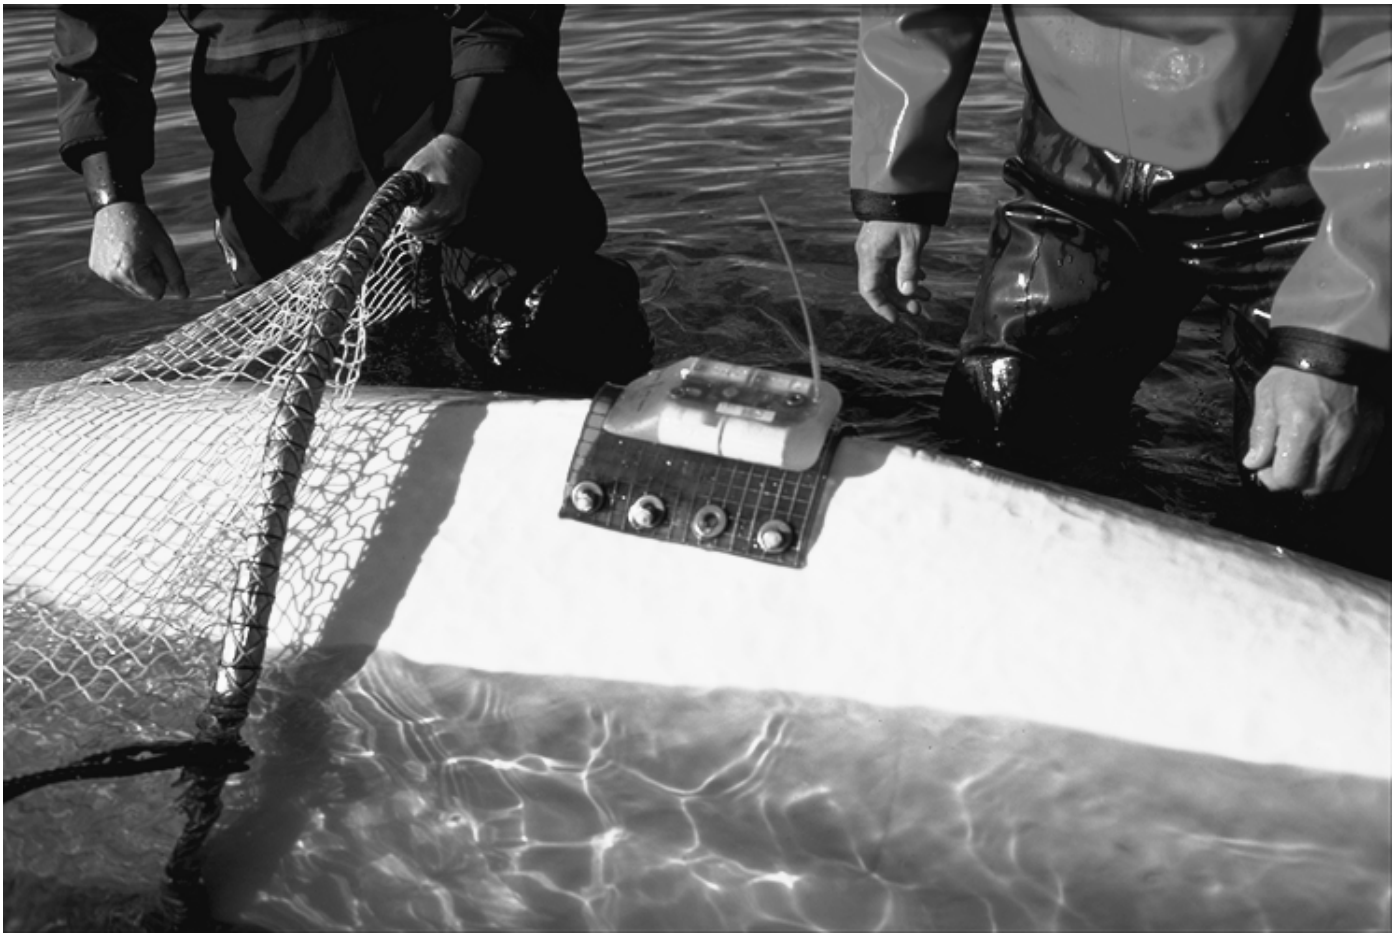

FIG. 2. Beluga equipped with a SLTDR tag pinned through the dorsal ridge. To the left is a hoop net used for live captures. (Photo: A. Rosing-Asvid)

speeds: a) for short time intervals (less than 0.5 hr), swimming speed estimates can be strongly biased downward or upward by errors in location; b) for intervals greater than 2 hr, estimates of swimming speed are biased downward when movements are not straight lines between the locations used to calculate travel distance. To reduce these biases, we calculated swimming speeds only for intervals between locations that were more than half an hour and less than two hours apart.

RESULTS

Tag Performance

The six tags transmitted for 37–60 days, sending between 17 695 and 26 089 signals (or "uplinks") to the satellites (Table 1). These signals produced good-quality locations (quality indices ≥ 1) for 33–55 days. The number of good quality locations varied among tags (Table 2) and declined with time in all six whales, resulting in fewer locations towards the end. Size or sex of the tagged animals did not appear to have influenced the longevity of transmissions since the two biggest animals, both males, had one of the longest and the shortest number of days of transmission (Table 1).

TABLE 2. Proportion of the quality 1–3 locations obtained from each tag.

		Locations			
Tag #	Total	Quality 1	Quality 2	Quality 3	Poor quality
20688 M	554	26.0%	14.6%	6.0%	53.4%
20689 F	567	18.0%	11.3%	4.8%	65.9%
20690 F	626	25.6%	15.5%	5.8%	53.1%
20694 F	526	18.3%	11.4%	3.2%	67.1%
20695 F	972	27.2%	16.7%	4.9%	51.2%
20696 M	1038	21.8%	10.2%	4.9%	63.1%

Distribution and Movements

All but one animal left Croker Bay and traveled east within a day of their release (Fig. 3). Female 20694 remained in Croker Bay for five days after release before heading east. Once out of Croker Bay, they all traveled close to shore along the southern and eastern coasts of Devon Island, reaching Hyde Inlet northwest of Philpots Island or Lady Ann Strait, eastern Jones Sound, and waters to the south of Coburg Island. All six animals entered Jones Sound and spent some time there. The two males went as far north as waters east of Clarence Head or Smith Bay, Ellesmere Island, while the four females remained south of Glacier Strait (Fig. 3).

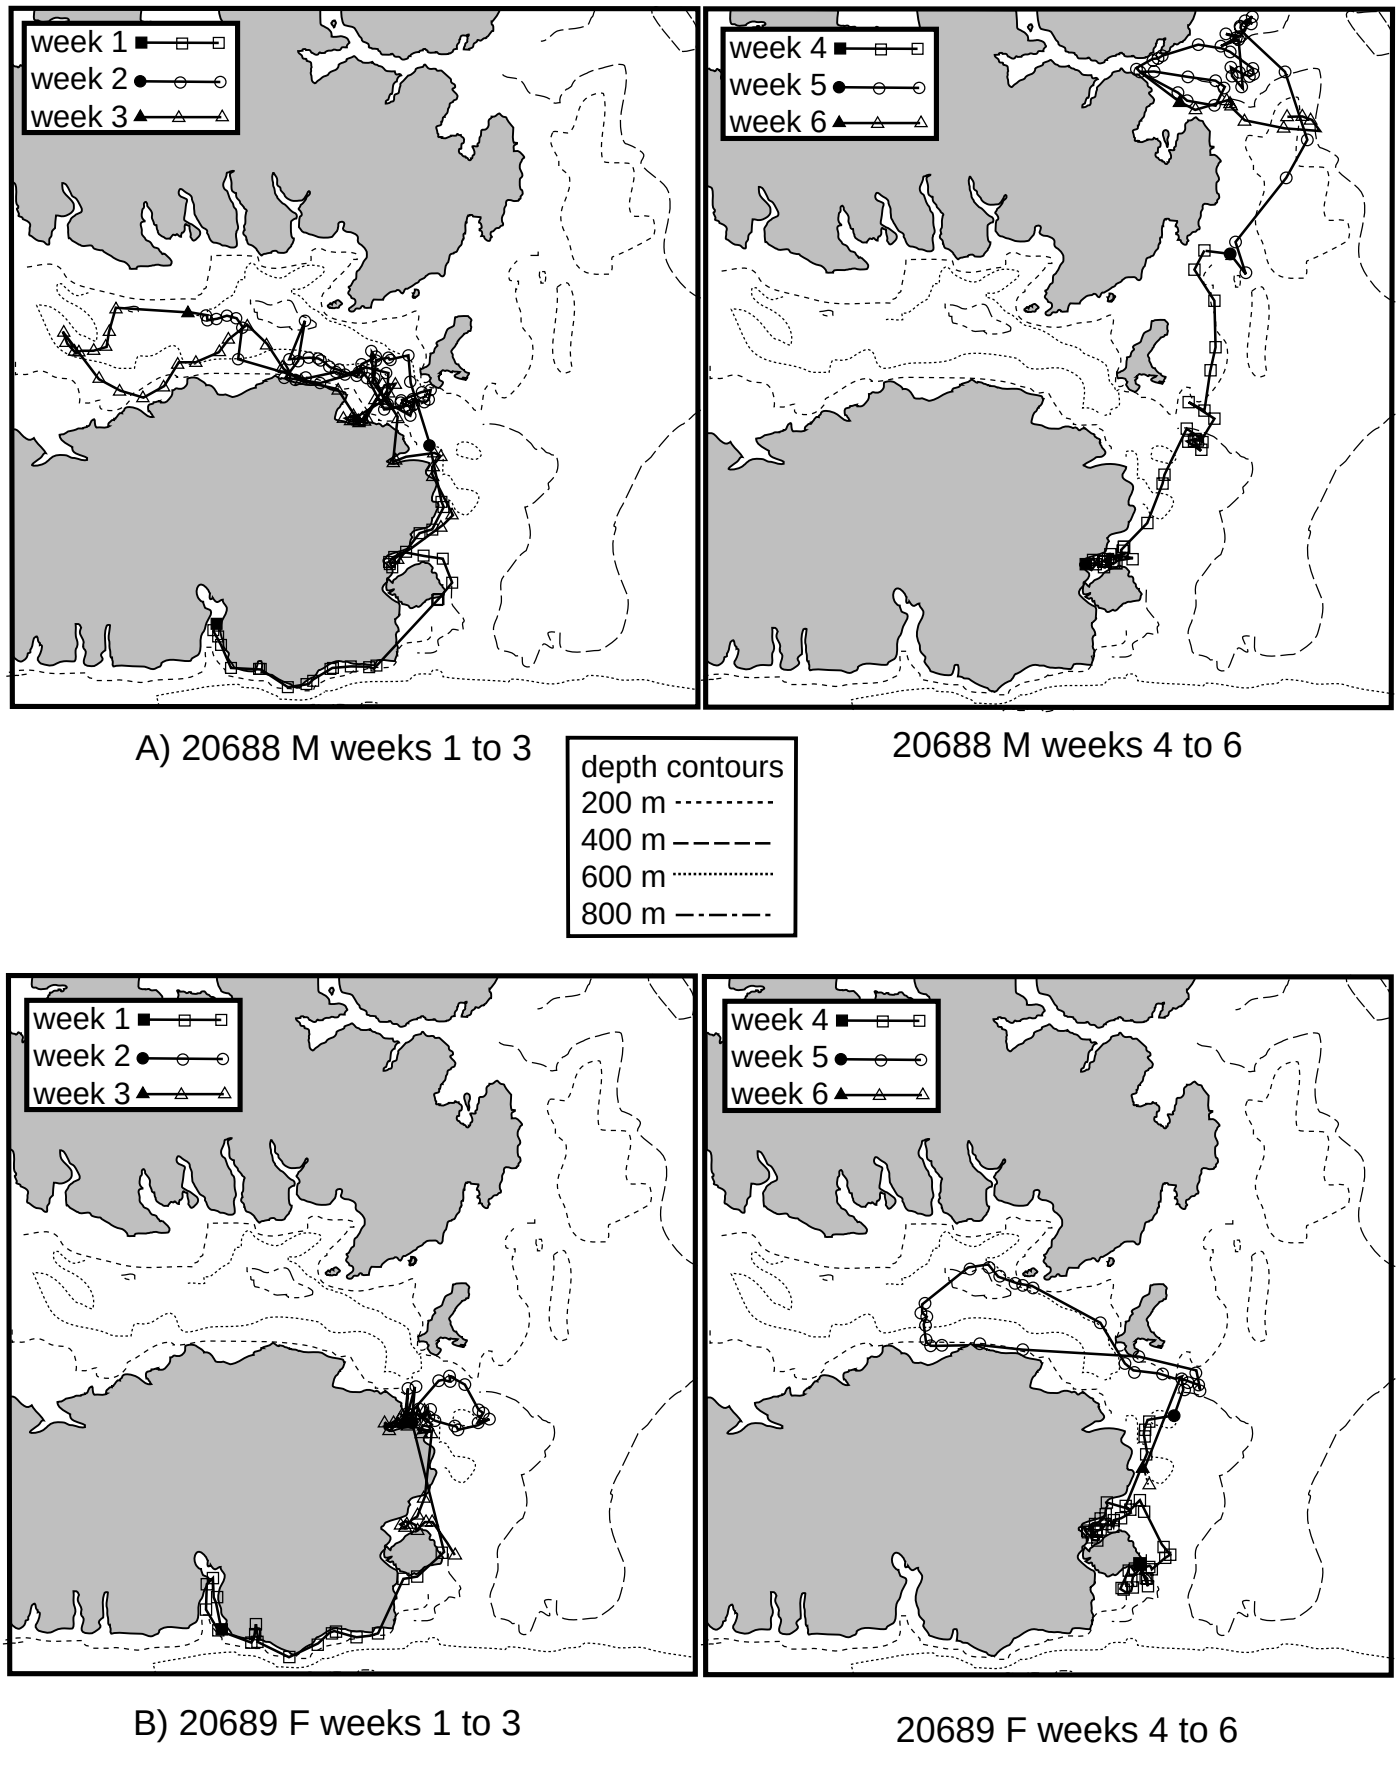

FIG. 3a and b. Weekly movements of the six tagged belugas, September to November 1995. The movement of each beluga is shown in two panels. Locations are plotted by calendar weeks (Sun-Sat). A different symbol is used to represent each calendar week. The first location in a calendar week is represented by a solid symbol; the remainder, by open symbols. Week 1 starts on 10 September 1995 and week 9 ends on 11 November.

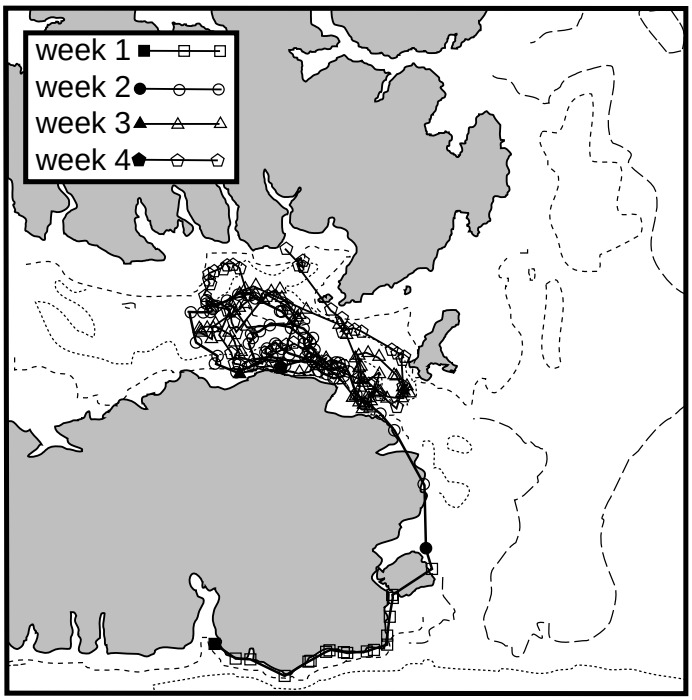
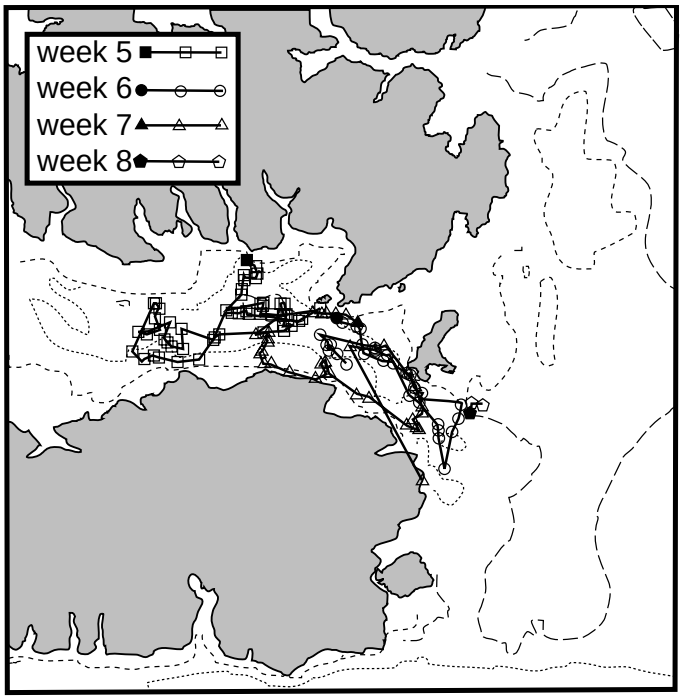
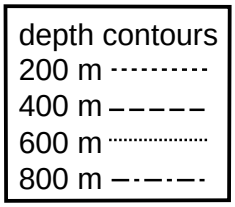
FIG. 3c and d. Weekly movements of the six tagged belugas, September to November 1995. The movement of each beluga is shown in two panels. Locations are plotted by calendar weeks (Sun-Sat). A different symbol is used to represent each calendar week. The first location in a calendar week is represented by a solid symbol; the remainder, by open symbols. Week 1 starts on 10 September 1995 and week 9 ends on 11 November.

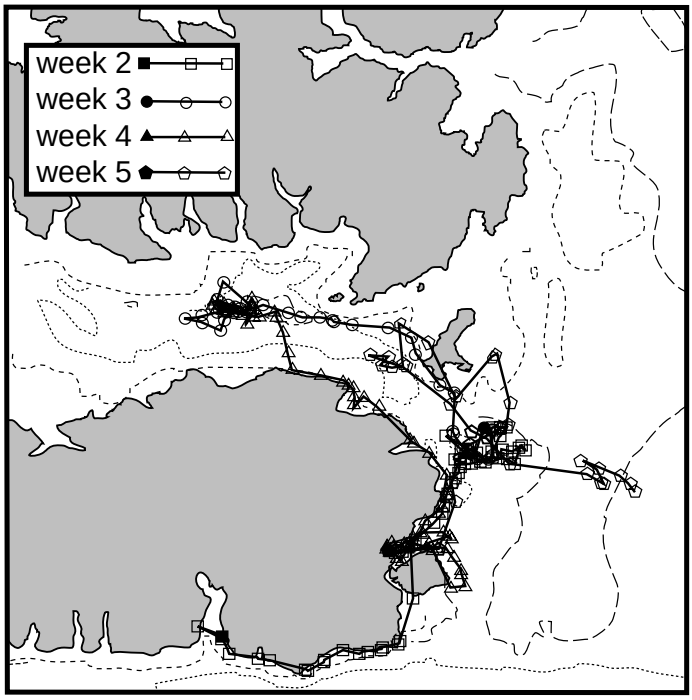


E) 20695 F weeks 1 to 4

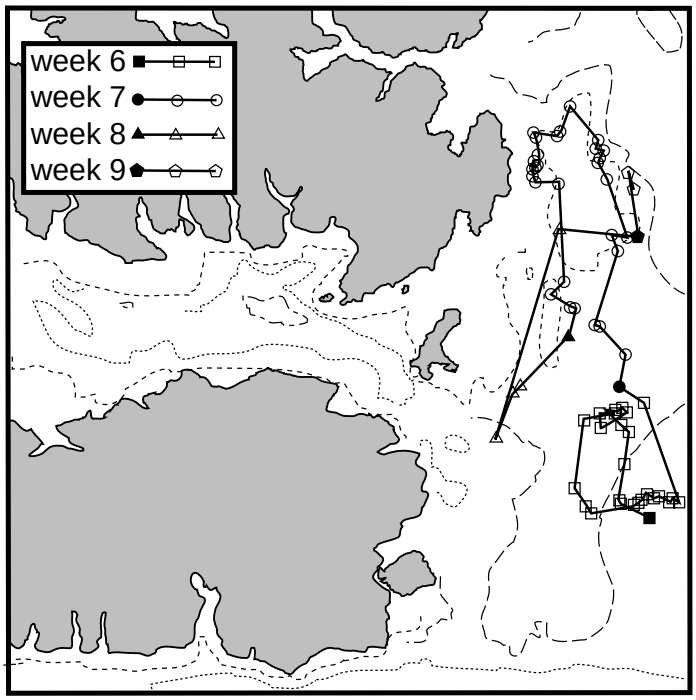


20695 F weeks 5 to 8





F) 20696 M weeks 2 to 5



20696 M weeks 6 to 9

FIG. 3e and f. Weekly movements of the six tagged belugas, September to November 1995. The movement of each beluga is shown in two panels. Locations are plotted by calendar weeks (Sun-Sat). A different symbol is used to represent each calendar week. The first location in a calendar week is represented by a solid symbol; the remainder, by open symbols. Week 1 starts on 10 September 1995 and week 9 ends on 11 November.

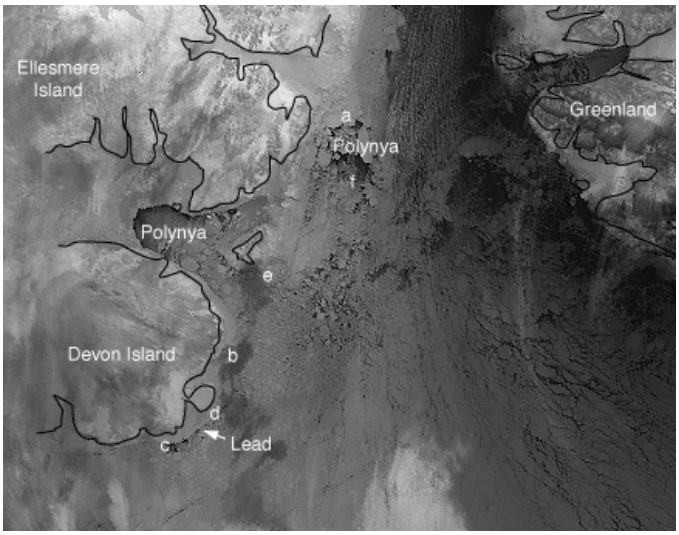


FIG. 4. NOAA satellite infrared image of the study area showing leads and polynyas of the North Water on 7 November 1995 (Source: Atmospheric Environment Service). Letters indicate the last recorded position of each animal: a) 20688M, b) 20689F, c) 20690F, d) 20694F, e) 20695F, f) 20696M.

Three areas were used by all six animals in the course of their movements: the southeastern shoreline of Devon Island, which all animals followed closely on their way east and north, and which was revisited by female 20690 in October; Lady Ann Strait and Jones Sound; and the waters southeast of Coburg Island. Two additional areas were used by some of the animals: Hyde Inlet, used by both males and female 20689; and the waters adjacent to Clarence Head, Ellesmere Island, used by both males.

Ice cover in the study area was greater than the median ice cover normally found at that time of year (Markham, 1981), and a lot of multiyear ice was mixed with newly formed ice. The tagged belugas traveled through ice cover varying between 2/10 and 9/10. Prior to ice consolidation (>9/10) in Jones Sound in early October, the whales moved to waters off eastern Devon Island, Coburg Island, and southeastern Ellesmere Island, where they could find ice leads and polynyas (Fig. 4).

None of the tagged belugas left Canadian waters during the period when the tags were operating, despite the fact that for all six whales transmissions lasted at least until mid-October, by which time belugas are typically seen migrating south along the West Greenland coast. Final recorded locations for all six whales came from the area of recurring winter leads and polynyas known as the North Water (Fig. 4).

Swimming Speeds

In most cases, estimated swimming speeds ranged from under 1 km/h to about 10 km/hr (Fig. 5). A few speeds (n = 7) were estimated at between 11 and 27.5 km/h. The mean swimming speeds of all animals combined decreased significantly from week to week (ANOVA $p = 0.002$). Four of the six animals (20688M, 20690F, 20695F, 20696M) showed a decline in weekly mean swimming speed over their period of transmission (Table 3). No swimming speeds greater than 6.3 km/h were recorded after October 15.

There was a significant interaction ($p = 0.0001$) in the ANOVA model between individual beluga and time (week) because two animals (20689F, 20694F) differed from the rest. Female 20689's weekly mean speeds showed no trend, and female 20694 stayed in Croker Bay during her first week, with resultant low swimming speeds. Her swimming speed increased in week 2 during her migration along the coast of Devon Island and declined thereafter in weeks 3 and 4 (Table 3). The sample size for 20694 was too small in weeks 5 and 6 to allow useful comparisons.

DISCUSSION

Soon after release, all but one of the tagged belugas moved to the eastern side of Devon Island, staying close to shore while migrating (Fig. 3). They occupied several bays of eastern Devon Island, such as Croker Bay, Bethune Inlet, Hyde Inlet, and unnamed bays opposite Lady Ann Strait, and later returned to these coastal areas after visiting Jones Sound. This coastal distribution pattern had previously been described by Koski and Davis (1979, 1980), who reported observing herds of hundreds and, in some cases, thousands of belugas along those shorelines and inside those bays. The fall concentrations of belugas in coastal areas of Devon Island may be related to the presence of arctic cod (*Boreogadus saida*), an important prey of belugas that occurs in large schools near shores in the Canadian High Arctic (Bradstreet et al., 1986). When discovered, such schools attract intense predation from birds and marine mammals, including belugas (Welch et al., 1993).

In deep fjords like Croker Bay, belugas may be foraging on other prey. Between 14 and 16 September, we observed hundreds of narwhals *(Monodon monoceros)* moving into Croker Bay. It is possible that both narwhals and belugas are attracted to Croker Bay by the same prey species. In addition to *Boreogadus saida*, narwhals are known to feed on Greenland halibut *(Reinhardtius hippoglossoides)* and on squid *(Gonatus fabricii)* in fjords of the Pond Inlet area (Finley and Gibb, 1982) and in Inglefield Bay, Greenland (Heide-Jørgensen et al., 1994).

All six tagged belugas spent between two and five weeks moving about eastern Jones Sound, Lady Ann Strait, and over the deep gully southeast of Coburg Island. The time-depth information shows that, while in those areas, the whales often dove to depths of 400–800 m or more, probably close to the seabed (Heide-Jørgensen et al., 1998). During those dives, it is probable that they were foraging for Greenland halibut, which usually occur at depths greater than 450 m (Scott and Scott, 1988). Greenland halibut remains have been observed by Grise Fiord hunters in ringed seal (*Phoca hispida*) holes and in the stomachs of hooded seals (*Cystophora cristata*) captured in Jones Sound (S. Akeeagok, Grise Fiord, pers. comm. 1995). Other potential deepwater prey are the squid (*Gonatus fabricii*) and the octopus (*Bathypolypus arcticus*).

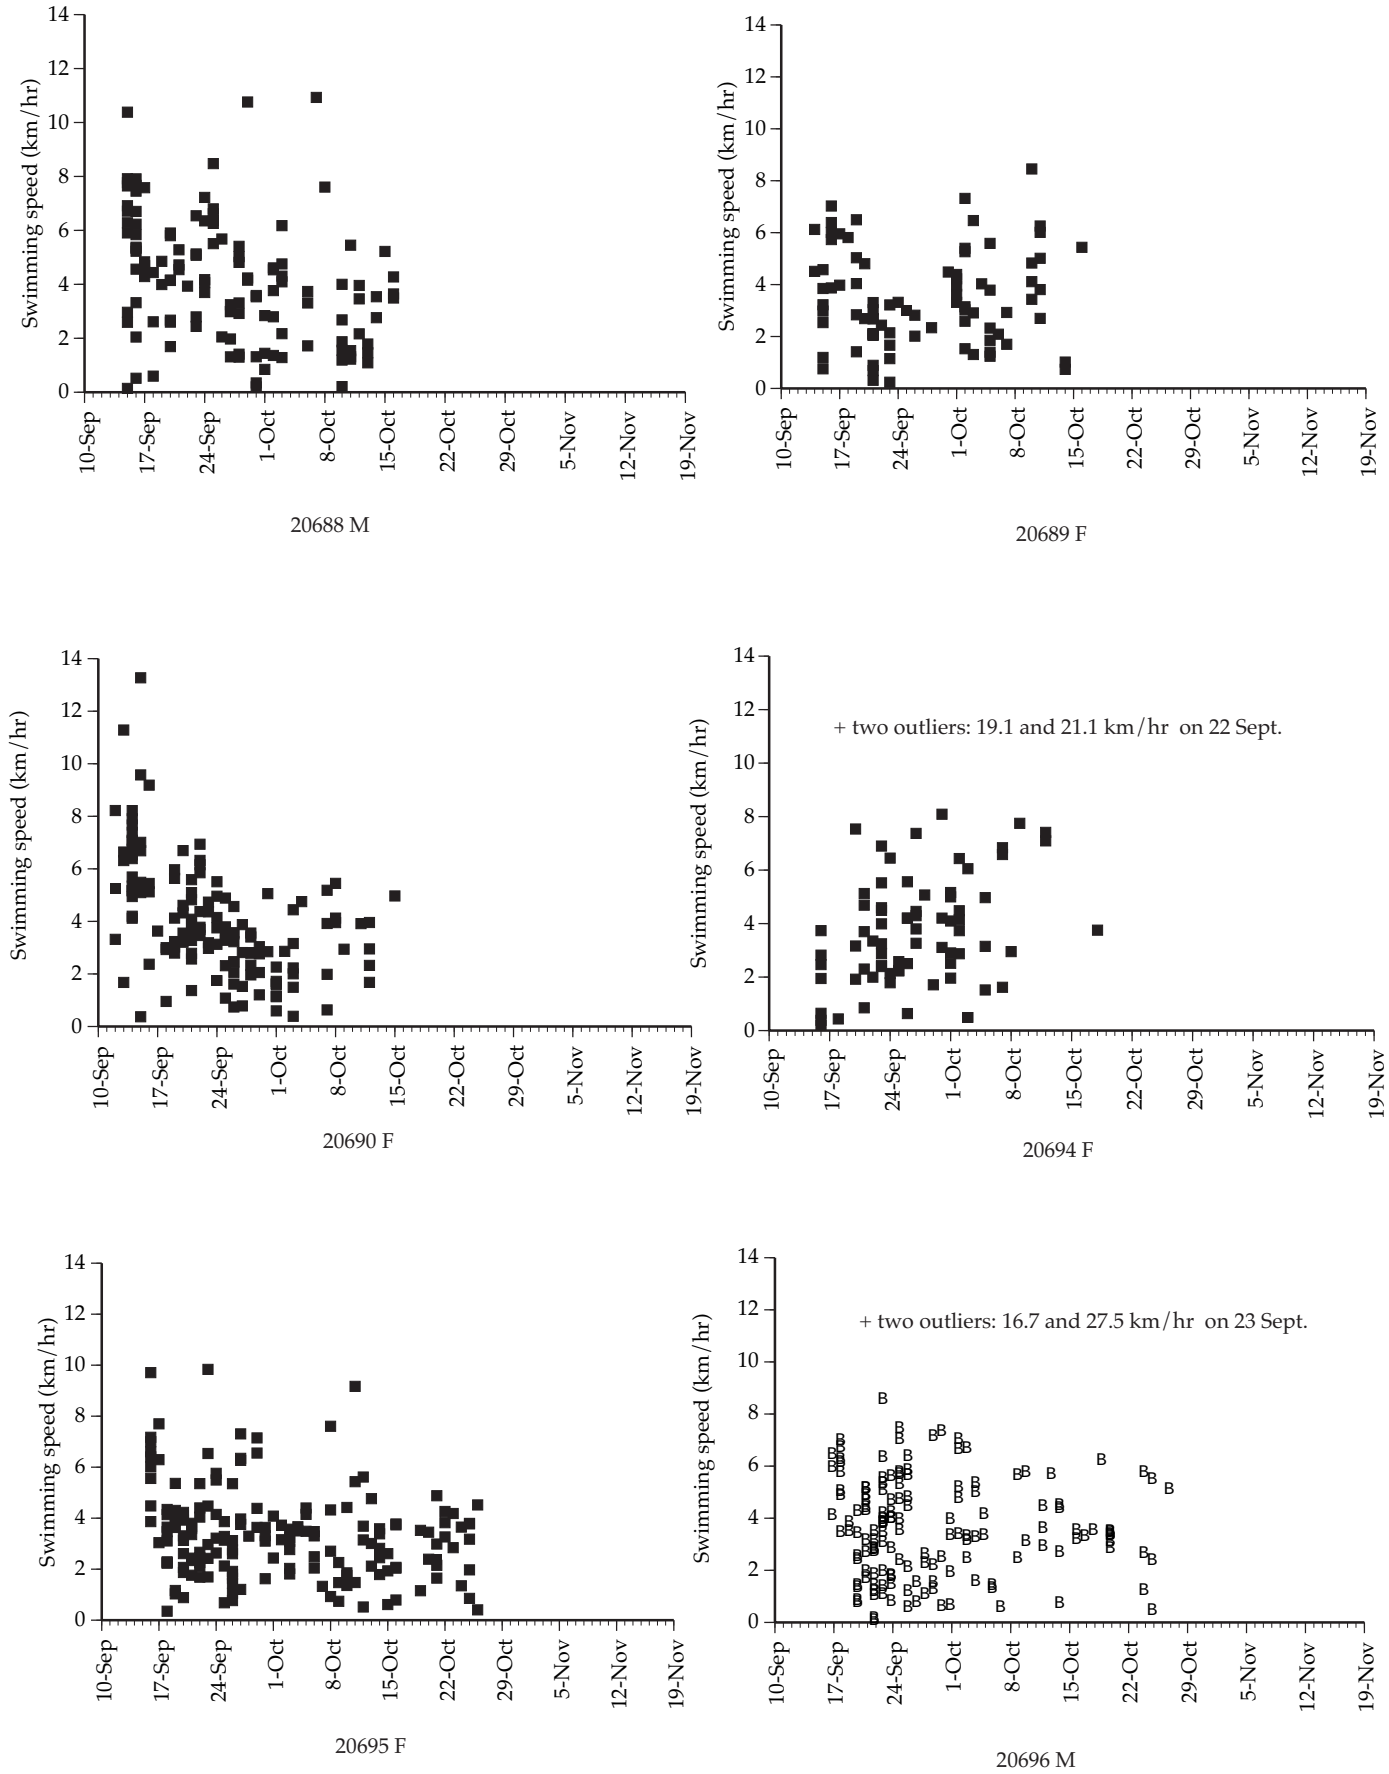

FIG. 5. Swimming speeds of tagged belugas over time.

TABLE 3. Mean weekly swimming speeds (km/h) of tagged belugas. Values are the mean, CV%, and (number of samples).

Beluga	WEEK

M 20696 408 cm	5.7 20% (11)	4.0 94% (67)	3.5 65% (29)	3.4 52% (15)	3.8 36% (12)	3.7 27% (9)	3.4 64% (7)	3.9 24% (150)

All six tagged belugas left Jones Sound before week 6 (15–21 October), avoiding entrapment in the consolidating pack ice. Consolidated pack ice can form over all of Jones Sound as early as mid-October (Markham, 1981), and there are reports of past ice entrapments of belugas in Jones Sound which have resulted in mortality (Freeman, 1968; S. Akeeagok, Grise Fiord, pers. comm. 1995).

The six tagged belugas remained in the waters east of Ellesmere, Coburg, and Devon Islands until their tags stopped transmitting. This area, known as the North Water (Smith and Rigby, 1981), has recurring leads and polynyas throughout winter where belugas are known to occur (Finley and Renaud, 1980; Richard et al., 1998). Therefore, in late October and November, the distribution of belugas was probably determined by the availability of open leads or cracks in the pack ice, as observed during winter aerial surveys of the North Water (Finley and Renaud, 1980; Richard et al., 1998). Both males traveled farther north along and off Clarence Head. This segregation between males and females could be due to the fact that all four females had calves with them and may have been less inclined than males to venture away from the predictable open leads off eastern Devon Island (Fig. 4).

Although we tracked animals only into October–November, we think that the tagged animals remained in the North Water for the winter, for two reasons. First, they stayed there well beyond the time when belugas are normally observed migrating along the West Greenland coast (Heide-Jørgensen, 1994; M.P. Heide-Jørgensen and A. Rosing-Asvid, Greenland Institute of Natural Resources, Copenhagen and Nuuk, unpubl. data). Second, the reduction in swimming speeds in October noted above and the decline in surface times and dive rates reported by Heide-Jørgensen et al. (1998) are what we expected to observe from belugas settling into their wintering area. Another possibility is that the belugas migrated to Greenland later in the winter, at a time when belugas would go unnoticed by residents of northern West Greenland because of the darkness and heavy ice.

The timing of our live captures could have influenced the results if belugas that migrate to Greenland move along the southern coast of Devon Island earlier than those that winter in the North Water. We had timed our captures for early to mid-September to match the timing of migration of Somerset Island belugas in Lancaster Sound reported by other authors (Koski and Davis, 1979, 1980; Smith and Martin, 1994). However, two weeks before our expedition, on 28 August 1995, a pod of belugas was seen in Jones Sound by Grise Fiord residents, (D. Akeeagok, Grise Fiord, pers. comm. 1995). Also, during the 10–11 September flights over Croker Bay (i.e., 3–4 days before we captured our first beluga there), we observed several thousand belugas in the bay. Therefore, the animals we sampled may not have been representative of all migrants. Thus our relatively small sample, which may have included some animals belonging to the same pods, is of limited value for describing the migratory behaviour of Baffin Bay belugas in the fall. There is a need to tag more animals to answer the question about movements to Greenland.

None of the beluga tags reached their full potential of 54000 transmissions at 0˚C (Wildlife Computers, 1994). Furthermore, the diagnostics sent by the tags gave no indications that a drop in battery voltage was responsible for the cessation of transmissions. Therefore, we assume that transmissions ended because of tag loss. The longevity of our tags (mean number of days between first and last position = 42, Table 1) is comparable with longevity in other satellite-tagging projects on monodontids. For example, backpack transmitters of the same design put on five narwhals by Dietz and Heide-Jørgensen (1995) gave positions between 2 and 41 days (mean = 25 days). Tags with a different design used in the Beaufort Sea by Richard et al. (1997) gave positions between 7 and 91 days (mean = 41 days).

The declining trend in good-quality locations in our tags may not be the result of deteriorating tag performance, since the power diagnostic data sent by the tags did not show a sufficient decline in power output. This decline in locations could be due in part to the seasonal trend in the belugas' activity and in part to the progressive detachment of the tags, which would affect antenna orientation. In October and November, the average time belugas spent at the surface was about half as much as in September (Heide-Jørgensen et al., 1998). Signal interference by ice could also be a contributing factor.

ACKNOWLEDGEMENTS

We are most grateful to Sylvain de Guise of l'Université du Québec à Montréal for his veterinary and live capture expertise. We thank Aqqalu Rosing-Asvid for his enthusiastic help in the field and his excellent photographs. Clyde Kalluk of Resolute was an excellent boatman and field assistant. We are indebted to Eric Doig of Renewable Resources, G.N.W.T., the Polar Continental Shelf Project, First Air, Jack Orr, and Patt Hall (DFO) for their logistic support. Ron Goodson of Atmospheric Environment Service provided support in obtaining NOAA imagery. We thank the Resolute and Grise Fiord Hunters and Trappers Committees for their support and interest. We thank Holly Cleator, Lloyd Lowry, and two anonymous reviewers for their review of earlier drafts. Jack Orr drafted all the figures. The Greenland Institute of Natural Resources, the Commission for Scientific Research in Greenland, the Nunavut Wildlife Management Board, the Sea Research Foundation, and the Department of Fisheries and Oceans funded this project. This is Contribution No. 107 from the Sea Research Foundation.

APPENDIX A: Vessel and Equipment Details
APPENDIX B: Physical Baseline Study – Northeast Baffin Bay
APPENDIX C: Review of the Effects of Airgun Sounds on Marine Mammals
APPENDIX D: Review of Potential Effects of Airgun Sound on Fish and Marine Invertebrates
APPENDIX E: Underwater Sound Propogation from an Airgun Array in Baffin Bay
APPENDIX F: Fundamentals of Underwater Sound
APPENDIX G: Summary of Calculations for Estimates of Percentage of Populations and Number of Individuals Exposed to Airgun Array Noise

NON-TECHNICAL SUMMARY

This section provides a non-technical summary of the Environmental Impact Assessment (EIA) for Shell's proposed 3-D (three-dimensional) seismic survey offshore northwest Greenland in July to October 2012. The summary provides an overview of the regulatory requirements, a description of the Project, an overview of the environmental setting, the methods used to assess impacts, proposed mitigation measures, predicted impacts of seismic noise and other Project activities, and it identifies data gaps and uncertainties.

1.1 Regulatory, Policy and Administrative Framework

The EIA was prepared to meet appropriate Greenlandic legislation and regulatory requirements, incorporate relevant international standards, and integrate Shell's policies. Key guidance documents used to prepare this EIA include:

- Bureau of Minerals and Petroleum (BMP) Guidelines for application, execution, and reporting of offshore hydrocarbon exploration activities (excluding drilling) in Greenland, December 2011 (BMP 2011).
- Guidelines to environmental impact assessment of seismic activities in Greenland waters, 3rd revised edition, December 2011 (Kyhn et al. 2011).

As required in the BMP Guidelines, Best Available Technology (BAT) and Best Environmental Practice (BEP; e.g., NORSOK, OSPAR, and MARPOL) were considered and incorporated into the Project where possible. Shell's Health, Safety, Security, Environment, and Social Performance Control Framework and Corporate Standards are incorporated into the Project and the EIA.

1.2 Project Description

Shell Kanumas A/S (Shell), acting as Operator on behalf of other oil and gas companies (Nunaoil, GDF SUEZ, and Statoil), is proposing to conduct a 3-D seismic survey program in the Anu (Block 5) and Napu (Block 8) licenses (see Figure 1-1). The objective of the survey is to obtain 3-D seismic data to identify potential targets for exploration drilling. The seismic survey is proposed to occur from mid July to mid October 2012. Water depths in the Seismic Area range from about 150 m to 700 m.

Two seismic ships (M/V *Polarcus Samur* and M/V *Polarcus Amani*) will be used to collect the data. Each ship will tow behind it two airgun arrays (each with a total volume of 4240 in^3) that will be activated in an alternating or "flip-flop" arrangement. The airguns emit short pulses of intense sound that are directed downward into the seafloor and the sound that echoes back is recorded on hydrophones located in streamers towed behind the seismic ships. Each ship will tow six 7-km long streamers spaced 200 m apart. The two seismic vessels will be supported by four chase vessels (typically two per seismic vessel), whose main task is ice management, and one supply vessel. The seismic vessels will maintain (as much as possible) a separation distance of at least 30 km when collecting seismic data. Each seismic vessel will have a total of about 50 crew members. The crew on the support vessels will be about 8–10 per vessel.

Shell proposes to collect seismic data along 118 survey lines (spaced 600 m apart and oriented in a north-south direction). The average length of each survey line is 120 km, which will require 15 h of surveying to complete; it will take the vessels 3.5–4 h to turn around to start the next survey line.

1.3 Environmental Setting

The EIA provides a general overview of the baseline conditions in and near the area where Shell proposes to collect seismic data. The Strategic Environmental Impact Assessment (SEIA) prepared for the Baffin Bay assessment area by the Danish Centre for Environment and Energy (DCE; Boertmann and Mosbech 2011) was a key source of information. Emphasis in Shell's EIA was placed on the biological and socioeconomic components that could be affected by Project activities. Information on fish, invertebrates, seabirds, marine mammals, commercial fisheries, subsistence fisheries and subsistence hunting was reviewed. As part of the review, the conservation status of species occurring in and near the Project Area as assessed in Greenland (Red List) and internationally was determined. Baseline conditions were reviewed, particularly the distribution and abundance of species and their activities (i.e., breeding, migrating, feeding) in and near the proposed Seismic Area.

The SEIA identified bowhead whales, narwhals, beluga whales, and walruses as the most sensitive species to seismic noise. The occurrence of bowheads, belugas, and walruses do not generally overlap with the period when Shell is proposing to conduct the seismic survey—the exception are belugas that migrate in October (and November) in coastal waters shoreward of the Seismic Area. Of most relevance to this EIA are narwhals that summer primarily in coastal waters of Melville Bay and which are considered *Critically Endangered* on the Greenland Red List. The Melville Bay population is estimated at about 6000 narwhals but this estimate is thought to be low. Narwhals migrate south to a deep basin of Baffin Bay from mid October to mid December, depending on the year; they feed there during the winter. A Narwhal Protection Zone (NPZ I) has been established in Melville Bay that restricts seismic surveys from 1 June to 15 October. Shell's primary Seismic Area is more than 30 km from this protection zone.

1.4 Impact Assessment Methods

The methods used to assess the impacts of the Project were based in part on those used in the SEIA prepared by the DCE (Boertmann and Mosbech 2011). Key aspects of the environment, typically called Valued Ecosystem Components (VECs) in EIAs, were selected for assessment including several marine mammals (narwhal, beluga whale, bowhead whale, walrus, ringed seal, bearded seal, and polar bear), seabirds, fish and invertebrates as well as their eggs and larvae. Commercial fisheries (mostly Greenland halibut and shrimp), subsistence fisheries, and the marine mammal subsistence hunt were considered VECs as well.

The primary aspect of the proposed activity causing concern is the underwater noise created by the airgun arrays and the impacts that such noise could have on narwhals and other marine mammals, including belugas. To understand the effect of this noise, Shell conducted acoustic modelling of the airgun array to estimate how far and at what sound levels this noise will travel. This information along with previous studies of how VECs respond to noise, allowed for predictions of whether the Project could have negligible, minor, moderate, or major impacts (magnitude); the size or spatial extent (km^2) of the impact; and how long an impact could occur (duration). Each impact prediction is accompanied by a level of confidence. Measures were identified to reduce or mitigate these impacts. All of these factors were used to assess whether the proposed Project could significantly affect a VEC. In this EIA, a significant impact is defined as having a major magnitude of any duration or spatial extent; or having a moderate magnitude for a duration of greater than one year and over a spatial extent greater than 100 km^2. The magnitude of impacts can be rated as:

Major:
An impact on a VEC is rated major if it is judged to result in a 10%, or greater, change in the size or health of a population or the carrying capacity of its habitat, or affect the subsistence resource to an extent that is not socially tolerated. A change in a population can result from an absolute reduction in population size or from displacement of animals to areas outside the area of consideration.

Moderate:
An impact on a VEC is rated moderate if it is judged to result in a 1–10% change in the size or health of a population or the carrying capacity of its habitat, or noticeably affect the subsistence resource involved; impacts would be socially tolerated.

Minor:
An impact on a VEC is rated minor if it is judged to result in a <1% change in the size or health of the population or the carrying capacity of its habitat, or only slightly affect the subsistence resource involved.

Negligible:
Negligible impacts would result in no to very minimal impacts to a VEC.

1.5 Summary of Potential Impacts and Mitigation Measures

The main Project activity of concern is the underwater noise emitted by the airgun arrays and this was the focus of the EIA for each VEC. Particular emphasis was given to narwhals as well as belugas and ringed seals, and the impacts of noise on their hearing and behaviour. Other Project activities like routine discharges of grey water (showers, wash water) and black water (treated sewage), and the physical presence of vessels were also assessed but are not included in this non-technical summary because impacts were considered negligible.

1.5.1 Mitigation Measures

As required by BMP an Environmental Management Plan was prepared that includes the monitoring and mitigation measures planned to reduce impacts. Mitigation measures incorporate BEP and BAT and as a minimum follow appropriate BMP guidelines and legislation; mitigation measures are summarized in Table 1-1.

Table 1-1.Summary of key mitigation measures.

Airgun Array Noise
Avoid Narwhal Protection Zone I
Avoid narwhal and beluga migration periods
Seismic vessels will maintain minimum separation distance of 30 km whenever possible
Use of 2-4 Marine Mammal and Seabird Observers (MMSOs) on each seismic vessel and 2 MMSOs on each support vessel
Use of a Passive Acoustic Monitoring (PAM) system to detect marine mammal calls in low visibility conditions
Ramp up of the array
Delay of ramp up for marine mammals seen or heard inside safety zone (800 m for whales and 500 m for other marine mammals)
Shutdown of airguns for marine mammals seen inside of safety zone
Shutdown of airguns during line changes
General Ship Operations
Vessels will steer a straight course and maintain a constant speed whenever possible
Reduce vessel lighting whenever it is safe and possible to do so to reduce chances of attracting seabirds
Rescue and release any stranded seabirds
Project vessel crews will keep a log of sightings and contacts with fishing (and other) vessels
Emissions and Discharges
All Project vessels will only use diesel and gasoil with a sulphur content of less than 1.5% (weight)
Vessels will meet or exceed regulations (MARPOL) for vessel discharges and emissions
Unplanned Events
Emergency Response, Spill Response (include bunkering procedures), and Ice Management Plans
Oil spill drills and oil spill kits
Use of solid streamers and double-hulled seismic vessels
Communications
Meet with stakeholders, including communities to provide information about the Project and its potential impacts
Notification of the seismic survey details to BMP, Royal Greenland A/S, shipping and harbour authorities, and hunter associations before the start of the survey
Establish a grievance mechanism that offers various ways (e.g., telephone, email, personal contact) to enable local stakeholders to contact Shell directly to ensure timely resolution of concerns and complaints
Start-up Meeting to ensure Shell and its Contractors fully understand mitigations
Shell will contact the DCE prior to survey start to ensure that its monitoring and mitigation plan for marine mammals and seabirds meets DCE protocols

1.5.2 Overview of Previous Studies

A thorough review of previous studies on seismic noise impacts for all VECs was conducted for the EIA. As noted earlier, the impacts of seismic noise on marine mammal hearing and behaviour were assessed in the EIA. There is some evidence that belugas can incur temporary hearing loss (or impairment) if they are exposed to seismic noise at close distances. There have been no studies of permanent hearing damage caused by seismic noise. There have been few studies of beluga whale response to seismic surveys and no such studies are available for narwhals. Seismic monitoring programs (Miller et al. 2005) involving intensive aerial surveys and ship-based observations were conducted in the Canadian Beaufort Sea in 2001–2002. Results suggest that belugas tended to avoid the area of seismic operations (a 3-D survey) by 10–20 km. There have been no studies of narwhal hearing impairment or changes in behaviour of narwhals attributable to airgun sounds. For that reason, studies of beluga whales were used to assess potential impacts on both belugas and narwhals.

1.5.3 Residual Impacts

After inclusion of the above-noted mitigation measures, there are no significant residual impacts predicted for the proposed 3-D seismic program (Table 1-2). The majority of the potential impacts (for routine activities, potential accidental spills of small fuel amounts, and airgun array noise) considered for VECs have a magnitude rating of *negligible, negligible to minor,* or *minor*—the exception is the predicted impact of airgun array noise on narwhal behaviour, which was ranked as moderate. Based on a series of precautionary steps, it was predicted that 1.1% of the Melville Bay narwhal population may avoid the airgun arrays when the seismic vessels are at their closest point to the Narwhal Protection Zone I. The proportion of narwhals affected decreases when the seismic vessels are surveying at farther distances from Melville Bay. Narwhals are not predicted to incur hearing damage from seismic noise given that narwhals (and other marine mammals) are expected to avoid at least the immediate area around the airgun arrays, and that mitigation measures (ramp up delays and airgun shutdowns in an 800 m safety zone) will reduce exposure to sound levels thought to be high enough to cause hearing damage. Similarly, belugas are not expected to incur hearing damage and residual impacts on hearing were assessed as *negligible*. The impact of seismic noise on beluga whale behaviour was judged as *minor*; it was predicted that 0.2% of belugas may avoid seismic noise during their fall migration period.

Table 1-2. Summary of impact predictions for VECs and airgun array noise.

Project Activity / VEC	Impact Magnitude	Significance	Level of Confidence
Airgun Array Noise			
Narwhals: hearing impacts	Negligible	Not Significant	High
Narwhals: behaviour impacts	Moderate	Not Significant	Medium
Belugas: hearing impacts	Negligible	Not Significant	High
Belugas: behaviour impacts	Minor	Not Significant	Medium
Other marine mammals: hearing impacts	Negligible	Not Significant	High

Project Activity / VEC	Impact Magnitude	Significance	Level of Confidence
Other marine mammals: behaviour impacts	Minor	Not Significant	High
Seabirds	Negligible	Not Significant	High
Marine mammal hunt	Minor	Not Significant	Medium
Fish and invertebrates (including eggs and larvae)	Minor	Not Significant	Medium
Commercial fisheries	Negligible to Minor	Not Significant	High
Subsistence fishery	Negligible to Minor	Not Significant	High

The level of confidence in predictions for impacts of airgun array noise is ranked as medium for narwhal and beluga behaviour because there is no information on how narwhals respond to seismic noise and beluga studies are limited. Similarly, a confidence level of medium was given for fish and invertebrates because of limited information available on the impacts of airgun array noise.

1.5.4 Cumulative Impacts

The potential for cumulative impacts from all activities proposed has also been assessed. In addition to Shell's proposed 3-D seismic survey, ConocoPhillips and Maersk Oil are proposing to conduct seismic surveys during July to September 2012 in the Qamut and Tooq licenses. In addition, a shallow coring program (led by Shell) involving one drilling vessel is proposed for August and September at 11 coring sites in and north of the Anu license. It is possible that marine mammals, including narwhals, could be exposed to noise from some or all of these seismic and shallow coring operations. It is highly unlikely that the cumulative impact of the three seismic programs and shallow coring program would affect 10% or more (i.e., the criterion for assigning an impact rating of "major") of narwhals in the Melville Bay area. It is far more likely that the combined programs might affect 2-4% of the narwhal population and that impacts would be *not significant*. The level of confidence in this prediction is low to medium as it is uncertain if cumulative impacts would be additive or whether habituation would occur and behavioural response distances would decrease. Because of this, a precautionary approach has been taken in this EIA.

1.6 Data Gaps and Uncertainties

One of the key data gaps in this EIA is the absence of information on how narwhals respond to seismic noise—this reduces the confidence in impact predictions. There is even more uncertainty in how multiple seismic programs and a shallow coring program will contribute to potential cumulative impacts on narwhals (and other VECs). Discussions have commenced regarding DCE/GINR-led studies designed to investigate the potential cumulative impacts assessed in this EIA, with emphasis on narwhals. Three studies are planned including those on sound travel of seismic noise, narwhal response to seismic noise, and the impacts of seismic noise on subsistence hunting in Melville Bay. Shell is committed to working closely with BMP, DCE and other Operators to facilitate a successful research program. This program will serve to address data gaps and provide a better basis for mitigation measures in future years.

2 INTRODUCTION

Shell Kanumas A/S (Shell), acting as an operator on behalf of Nunaoil, GDF SUEZ, and Statoil, is proposing to conduct a 3-D seismic survey program offshore northwest Greenland in 2012. The seismic survey would involve the use of two seismic vessels to acquire 3-D survey data in the Anu (Block 5) and Napu (Block 8) licenses. The seismic survey is proposed to occur from mid-July to mid October 2012. This document is the Environmental Impact Assessment (EIA) prepared for the Greenland Bureau of Minerals and Petroleum (BMP) as part of the application process to acquire an approval to conduct offshore hydrocarbon exploration activities under the *Mineral Resources Act* (Section 86; BMP 2011). The EIA has been prepared in accordance with BMP's "Guidelines for application, execution and reporting of offshore hydrocarbon exploration activities (excluding drilling) in Greenland" (BMP 2011) and "Guidelines to environmental impact assessment of seismic activities in Greenland waters, 3rd revised edition, December 2011" (Kyhn et al. 2011).

2.1 Proponent

Shell is the operator for the proposed 3-D seismic survey program in the Anu (Block 5) and Napu (Block 8) licenses. Shell has acquired extensive operating and development experience in arctic and sub-arctic regions for over 40 years, and has developed the technology and expertise required to operate safely and effectively in remote and extreme conditions. In 2011, Shell, on behalf of a consortium of oil and gas companies, successfully conducted a geophysical site survey in and north of the Anu and Napu licenses. As part of the geophysical site survey, a marine mammal and seabird monitoring and mitigation program was implemented, and valuable data were collected that inform this EIA.

2.2 Scope

This EIA has been prepared to meet the applicable requirements of Greenland legislation and standards, and also follows appropriate international guidance and best practice. The most relevant legislation, standards, and guidance are referenced in Section 3. The geographical scope of this EIA includes the Anu and Napu licenses and a larger area where potential impacts of the Project could occur (i.e., the Study Area, as defined in Section 6.2; see Figure 4.1 later). LGL Limited, environmental research associates, in association withGrontmij A/S, prepared this EIA. Operational and management information was provided by Shell.

The purpose of this EIA is to

- Provide details of the Project;
- Describe the environmental components and commercial fisheries and subsistence harvesting activities within the Study Area;
- Identify and assess the nature, significance, and probability of potential environmental impacts associated with the proposed 3-D seismic survey; and
- Describe appropriate mitigation measures in the Environmental Management Plan (EMP), together with management and monitoring procedures that will seek to avoid or reduce potential impacts.

The following sections are included as part of this EIA:

- Section 1: Non-technical summary
- Section 2: Introduction (this section)

- Section 3: Regulatory, Policy and Administrative Framework
- Section 4: Project Description
- Section 5: Description of the Environment
- Section 6: Impact Assessment
- Section 7: Environmental Management Plan
- Section 8: Literature Cited

A number of technical appendices containing supporting information relevant to the EIA, such as technical vessel specifications, review of the physical environment, and detailed literature reviews on the effects of seismic noise on marine mammals and fish/invertebrates, are included in support of this EIA and referenced within the text.

3 REGULATORY, POLICY AND ADMINISTRATIVE FRAMEWORK

This EIA was prepared to meet appropriate Greenlandic legislation and regulatory requirements, incorporate relevant international standards, and integrate Shell's policies.

3.1 National Legislation and Guidelines

The following Greenlandic legislation and regulatory requirements for offshore petroleum exploration and environmental protection apply to the proposed 3-D seismic EIA and to the associated EMP. [This list is not meant to be exhaustive but does provide the key legislation and guidance documents relevant to the proposed seismic EIA.]

- Greenland Parliament Act no. 7 of 7 December 2009 on mineral resources and mineral resource activities (the Mineral Resources Act).
- BMP Guidelines for application, execution, and reporting of offshore hydrocarbon exploration activities (excluding drilling) in Greenland, December 2011 (BMP 2011).
- Guidelines to environmental impact assessment of seismic activities in Greenland waters, 3rd revised edition, December 2011 (Kyhn et al. 2011).
- NERI (DCE) and BMP Manual for seabird and marine mammal survey on seismic vessels in Greenland, May 2011 (Johansen et al. 2011a).
- Act no. 929 of 24 September 2009 issued by the Danish Environmental Protection Agency on the Protection of the Marine Environment (replacing Act no. 476 of 30 June 1993 on the Protection of the Marine Environment).
- Greenland Home Rule Executive Orders including those for protection and hunting of polar bears, walrus, and birds.
- Greenland Government Executive Orders including those for protection and hunting of large whales, seals, belugas and narwhals.

3.2 International Treaties, Conventions and Best Practice

As required in the BMP Guidelines (2011), Best Available Technology (BAT) and Best Environmental Practice (BEP) must be considered and incorporated into a seismic program where possible. International BEP Guidelines (e.g., NORSOK standards), international conventions (e.g., OSPAR), and IMO Conventions (e.g., MARPOL) have been used in the development of the EMP (see Section 7 for details).

3.3 Shell Environmental Management

The Project will be conducted within the framework of Shell's internal standards and Business Principles, as well as the environmental, health, and safety policies and procedures of its subcontractors. Environmental, Health and Safety management of the Project will follow the procedures and requirements as described in Shell's HSSE & SP Control Framework and Corporate Standards (Health, Safety, Security, Environment, and Social Performance; Table 3-1).

These policies and management procedures will be bridged to the contractors' own management system. Specifically regarding offshore seismic, Shell requires the Project to meet

- OGP HSE Aspects in a Contracting Environment for Geophysical Operations (2001);
- IAGC Environmental Guidelines for World-wide Geophysical Operations (2001); and
- IAGC Recommended Mitigation Measures for Cetaceans during Geophysical Operations (2001).

Table 3-1. Shell commitment and policy on health, security, safety, environment and social performance.

Commitment	Policy
Shell is committed to: • Pursue the goal of no harm to people; • Protect the environment; • Use material and energy efficiently to provide our products and services; • Respect our neighbours and contribute to the societies in which we operate; • Develop energy resources, products and services consistent with these aims; • Publicly report on our performance; • Play a leading role in promoting best practice in our industries; • Manage HSSE & SP matters as any other critical business activity; and • Promote a culture in which all Shell employees share this commitment.	**Every Shell Company:** • Has a systematic approach to HSSE & SP management designed to ensure compliance with the law and to achieve continuous performance improvement; • Sets targets for improvement and measures, appraises and reports performance; • Requires contractors to manage HSSE & SP in line with this policy; • Requires joint ventures under its operational control to apply this policy, and uses its influence to promote it in its other ventures; • Engages effectively with neighbours and impacted communities; and • Includes HSSE & SP performance in the appraisal of staff and rewards accordingly.

4 PROJECT DESCRIPTION

Shell is proposing to conduct a 3-D seismic survey program in portions of the Anu and Napu licenses from mid July to mid October 2012 (see Figure 4-1). The proposed 3-D seismic survey will be conducted by the seismic contractor Polarcus Seismic Limited (Polarcus). The seismic program is described below and provides information required in BMP's "Guidelines for application, execution and reporting of offshore hydrocarbon exploration activities (excluding drilling) in Greenland" (BMP 2011). As required in these BMP Guidelines, BAT and BEP have been incorporated into the survey design and vessel and equipment selection to minimize environmental impacts. This is discussed in detail in the EMP (see Section 7 later in the EIA).

4.1 Project Scope and Objectives

Shell is proposing to acquire ~8,637 km^2 of 3-D seismic data in 2012 to evaluate hydrocarbon reserves in the Anu and Napu licenses. An additional ~1,650 km^2 of 3-D seismic data could also be acquired (see "Optional" areas shown in Figure 4-1) if time and ice conditions permit. In order to acquire full-fold migrated seismic data in the Anu license, limited seismic data will be acquired in the adjacent Pitu block, and potentially the Qamut block as well.

4.2 Program Description

4.2.1 Survey Program and Schedule

The timing of operations is highly dependent on ice conditions. Project vessels are estimated to enter Greenland waters around 10 July 2012. It is expected that the vessels will begin seismic data acquisition by ~15 July. Survey completion is planned by 15 October 2012, after which time the vessels are expected to demobilize. The 15 October survey completion is planned because of the protection period (15 October–1 December) established for narwhals in Narwhal Protection Zone II, which overlaps with the Project Area. Table 4-1 provides the survey data requested in the Seismic EIA Guidelines (Kyhn et al. 2011).

The 3-D seismic data will be acquired by two seismic vessels (M/V *Polarcus Amani* and M/V *Polarcus Samur*) owned and operated by Polarcus Seismic Limited. Each seismic vessel will use identical airgun arrays (4240-in³ total volume; details provided in Section 4.2.4) and streamers (six solid streamers spaced at 200 m, 7 km in length; details provided in Section 4.2.5). The two seismic vessels will be supported by four chase vessels (typically two per seismic vessel), whose primary task is ice management, and one supply vessel. The seismic vessels will work independently, but will coordinate closely to maintain as much as possible a separation distance of at least 30 km when acquiring seismic data, in order to minimize seismic interference levels.

TABLE 4-1. Survey data for Shell's 3-D seismic survey (as per Table 6.4.1 required in Seismic EIA Guidelines; Kyhn et al. 2011).

Specify	Description	Provided
Type of survey (2-D, high resolution (3-D), well testing, other)	3-D seismic survey	Yes
Map of the area with all transect lines	See Figure 4-2	Yes
Start and end dates for the survey	15 July–15 October 2012 (estimated)	Yes
Expected duration	3 months	Yes
Duty cycle of operation (in hours/ 24 hours). Number of hours in the dark per 24 hours.	Duty cycle 24/7. Number of hours of darkness in July and August: 0 h; September: 8 h; 1-15 October: 12 h	Yes
Number and types of accompanying vessels	One supply vessel and four chase vessels (all ICE-1A class)	Yes
Intended use of icebreakers. Will survey be carried out in ice?	No icebreakers will be used. The seismic survey can only be conducted in mostly open water.	Yes

Survey Design

Within the primary "Seismic Area", Shell proposes to acquire ~8,637 km^2 of 3-D seismic data. The seismic survey lines (118 survey lines spaced 600 m apart; ~14,388 line km in total) are oriented in a north-south direction in the Seismic Area (Figure 4-2). In order to acquire full fold seismic data, it is necessary to acquire shotpoints over a distance equal to half the streamer length (i.e., 3.5 km) at the end of each seismic line. Whether these shotpoints are taken at the northern or southern end of the Seismic Area depends on the shooting direction of each individual survey line, which is not presently known.

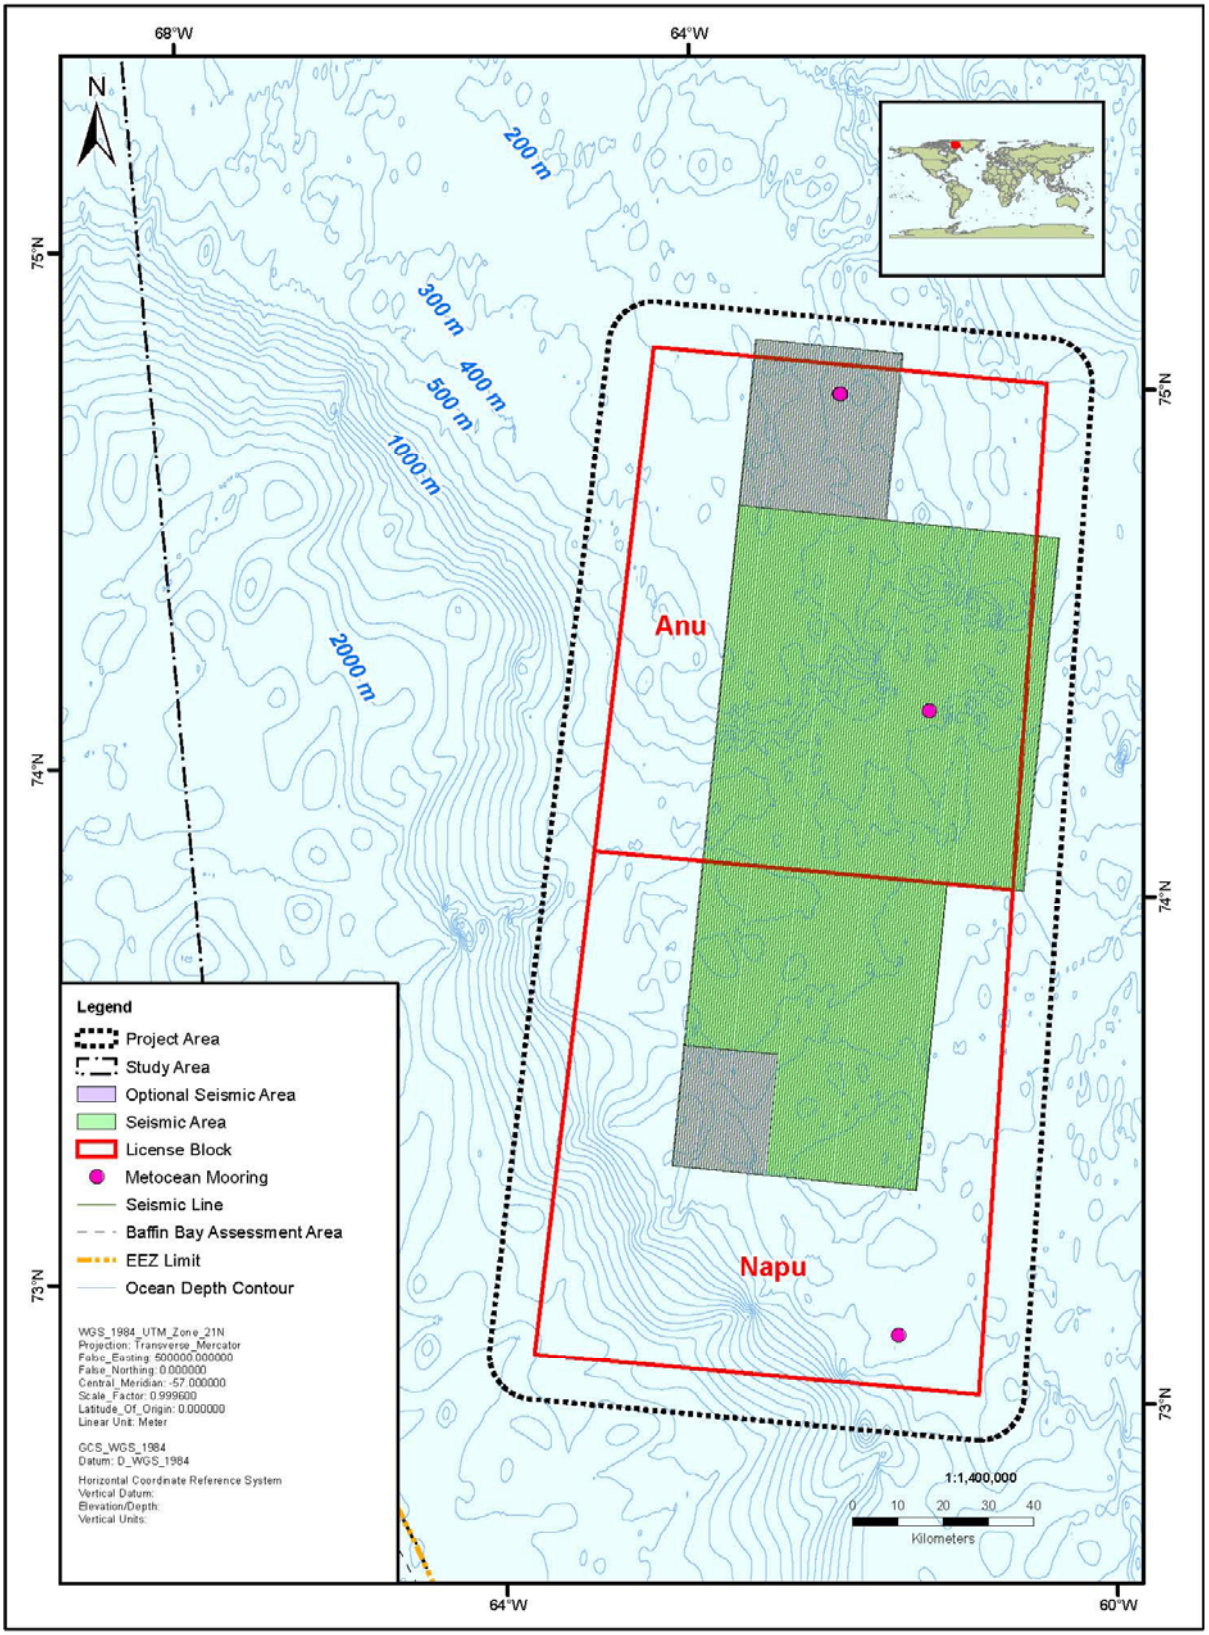
Shell's current plan is that the Seismic Area will be divided into east and west portions, i.e., an "East Block" and a "West Block". It is proposed that each of the seismic vessels will start on the eastern side of their respective block, as there is likely to be sea ice remaining in the west and southwest parts of the Seismic Area at the start of the planned survey. As ice conditions permit, the seismic vessels will move to the western portion of their blocks to acquire data in the ice-free waters.

As noted earlier, an additional ~1,650 km^2 of 3-D seismic data could also be acquired in two Optional Areas (Figure 4-1) if time and ice conditions permit. For efficiency reasons, an early judgment will be made as to whether data in the Optional Areas can be acquired or not. At the start of the survey, an attempt may be made to acquire data in either one or both of the Optional Areas. If the seismic production (forecast) is below expectations, only the primary Seismic Area will be surveyed.

The seismic vessels will survey at a speed of ~4.3 knots (8 km/h). Under normal operational conditions, the average length of each survey line is 120 km, which will require 15 h of surveying. It is estimated that line changes will require 3.5–4 h to complete. Each seismic vessel will alternately activate their two airgun arrays at an inline spacing of 25 m (i.e., 50 m for each source), or ~11 s (22 s each source).

Operation of Two Seismic Vessels

Shell is proposing to operate two seismic vessels simultaneously. In order to reduce the level of seismic interference between the seismic vessels, which has a negative effect on data quality, two measures will be taken. First, as much as possible, a minimum distance of 30 km will be maintained between the two seismic vessels during data acquisition. Second, the firing time of airgun arrays on one vessel (the 'slave vessel') will have a random jitter in relation to the firing time of the airgun arrays on the other vessel (the 'master vessel'). The magnitude of the jitter will be a maximum of~0.25–0.5 s.



GSI B.V. - THE HAGUE **Author: Mark Fitzgerald** **Date: 02/21/2012** **Draw. No: 1**	**Shell Baffin Bay 3D Seismic** **Survey lines for the proposed Shell Baffin Bay 3D seismic program in 2012.**	**FIGURE No.** **4-2**

Copyright 2011 GSI B.V.

Other Data Collection
Each seismic vessel will collect bathymetry and gravity data, and possibly magnetic data. Sound speed profile data will be acquired on a weekly basis. The collection of these types of data is standard practice during marine seismic surveys.

Other Activities
The supply vessel will retrieve three metocean moorings that were deployed by Shell in 2011 (two of the locations are shown in Figure 4-2 and the third mooring is located in the southeast corner of the Napu license). These metocean moorings were deployed to measure ice cover and thickness. After servicing and recalibration, these moorings could be redeployed at the same approximate locations and retrieved the year after. There are no plans to conduct seabed sampling during the seismic program.

4.2.2 Seismic Vessels

The seismic survey will be conducted by two seismic vessels, the M/V *Polarcus Samur* and M/V *Polarcus Amani*. Both vessels are newly built, environmentally advanced vessels that have diesel-electric propulsion, high specification catalytic convertors, double hull, and advanced ballast-water treatment and bilge-water cleaning systems.

M/V *Polarcus Samur*
The *Polarcus Samar* (ICE-1A class; call sign C6XK8; Figure 4-3) was built in 2011 and is owned by Polarcus Samur Ltd. and registered in the Bahamas. It is 84.2 m long, with a beam of 17 m and a maximum draft of 6.7 m. The *Polarcus Samar* has cruising and maximum speeds of ~28 km/h (15 knots) and ~31 km/h (17 knots), respectively, but will travel at a speed of 8 km/h (4.3 knots) while conducting seismic surveying. The vessel is equipped with state of the art navigation, radar, communication and depth sounding equipment, bow and stern thrusters, and a Dynamic Positioning (DP) system. It has a fuel capacity of 1025 m^3 of gas-oil. It will have appropriate on-board environmental protection equipment or systems, and will house Marine Mammal and Seabird Observers (MMSOs). Appendix A provides more details about this vessel.

M/V *Polarcus Amani*
The *Polarcus Amani* (ICE-1A Super class; call sign C6ZD3) will be completed in 2012, and is owned by Polarcus Amani AS. It is 92 m long, with a beam of 21 m and a maximum draft of 7.5 m. The *Polarcus Amani* has a maximum cruising speed of ~30 km/h (16 knots) but will travel at a speed of 8 km/h (4.3 knots) while conducting seismic surveying. The vessel is equipped with state of the art navigation, radar, communication and depth sounding equipment, bow and stern thrusters, and a DP system. It has a fuel capacity of 1925 m^3 of gas-oil. It will have appropriate on-board environmental protection equipment or systems, and will house MMSOs. Appendix A provides more details about this vessel.

4.2.3 Support Vessels

The two seismic vessels will be supported by one supply vessel and four chase vessels; each of these support vessels will be ICE-1A class (or higher). The supply vessel will provide the seismic vessels with fuel, water, food, and materials. The main task of the chase vessels is to aid in ice management. At the time of this submission, the names of the support vessels cannot be confirmed. Information on the support vessels will be provided to BMP when it becomes available (most likely in March).

FIGURE 4-3. Seismic vessel M/V *Polarcus Samur*.

4.2.4 Seismic Source Array

Each of the *Polarcus Samur* and *Polarcus Amani* will tow two airgun arrays that will be activated in a flip-flop arrangement. The airgun arrays are deployed ~400 m astern of the vessels, and are towed at a separation of 100 m. Each array consists of three sub-arrays. Each sub-array consists of 12 airguns, one of which is considered a spare (i.e., a total of 33 active airguns for each of the two arrays). The total volume of each array will be 4240 in³ with individual airgun sizes ranging from 45 to 380 in³. Each array is operated at 2000 psi and has a broadband source level in the vertical direction of 262.6 dB re 1µPa (peak to peak) (as estimated by acoustic modelling; see Section 6.7). The arrays will be towed at a depth of 8 m, although this is possibly subject to minor adjustment. Table 4-2 and Figures 4-4 and 4-5 provide additional details on the airgun array. Acoustic properties of the airgun array required in the Seismic EIA Guidelines are provided in Section 6.7.

The 4240-in^3 array is required because it provides sufficient power required to collect seismic data at the deepest geological targets (Cretaceous) of the survey, which are 5–6 km below the seabed.

4.2.5 Recording Streamers

Six solid seismic streamers, each 7 km long, separated by a distance of 200 m, will be towed behind each seismic vessel (see Figure 4-6). The streamers contain sensors (hydrophones) spaced at ~1.8 m. Solid streamers will be used, so there is no risk of fluids being discharged, as could be the case with fluid filled streamers. Streamers will be deployed 9–11 m (to be decided) below the water surface, and each streamer will be equipped with a tail buoy that is used for positioning purposes.

The proposed geometry of six streamers spaced 200 m apart is close to the maximum towing width possible in the geophysical industry. A streamer spread of 12 streamers (as recommended by BMP in response to Shell's submission of Scope of Project document) at 200 m, for example, is not possible with present-day technology, nor desirable as the data quality would suffer greatly, based on modelling conducted by Shell.

TABLE 4-2. Array specifications for Shell's 3-D seismic survey (per Table 6.4.2 required in Seismic EIA Guidelines; Kyhn et al. 2011).

Specify	Description	Provided
Number and names of vessels towing airgun arrays	Two seismic vessels: M/V *Polarcus Amani* and M/V *Polarcus Samur*	Yes
For each vessel provide geometric layout of complete airgun array with individual volume specified (in psi per airgun and in^3 per airgun)	See Figure 4-4[a]	Yes
Size of total array (in^3 and psi for the entire array)	4240 in^3 and 2000 psi	Yes
Firing rate in shots/sec. Will sub arrays fire simultaneously or alternate?	For each vessel, shotpoint every 11 sec or 0.09 shots/sec. Arrays alternate.	Yes
Operation speed of the vessel in km/hours or knots.	8 km/h (4.3 knots)	Yes

[a] Each airgun is operated at the same pressure, i.e., 2000 psi.

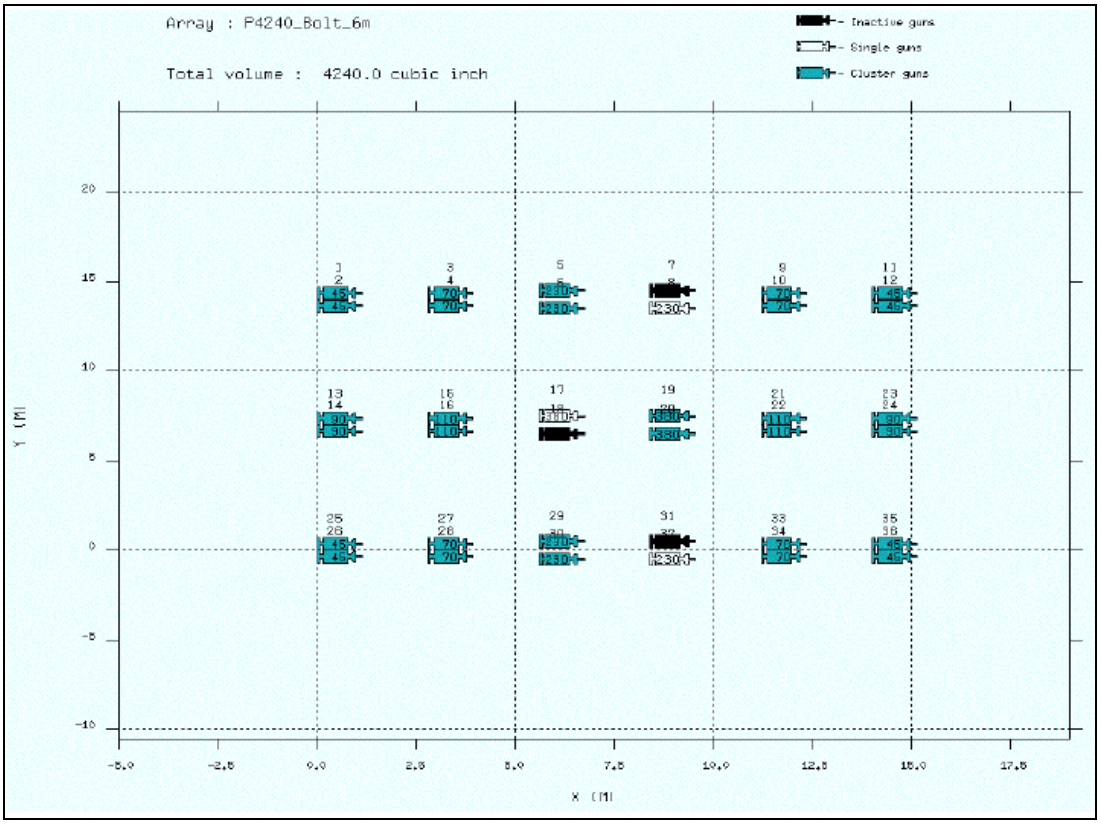


FIGURE 4-4. Geometric layout of airgun array.Volumes of each airgun are shown inside the airgun schematic (volumes range from 45 to 380 in^3); airguns shaded black are considered spares.

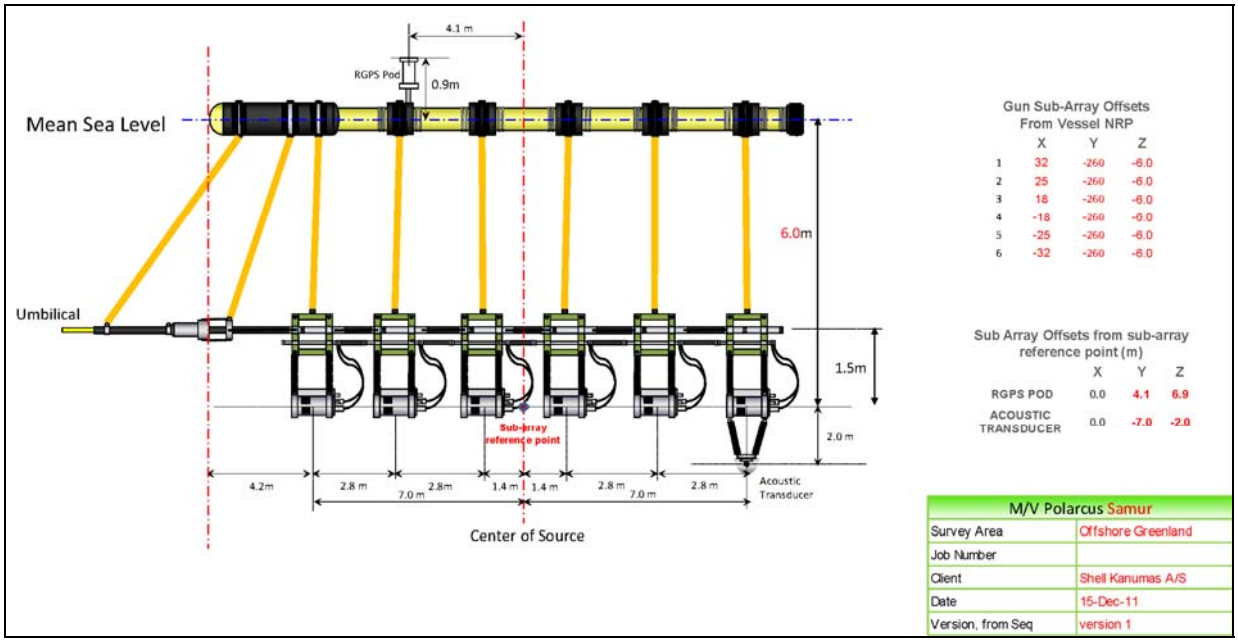

FIGURE 4-5. Schematic of airgun sub-array (identical on both seismic vessels).

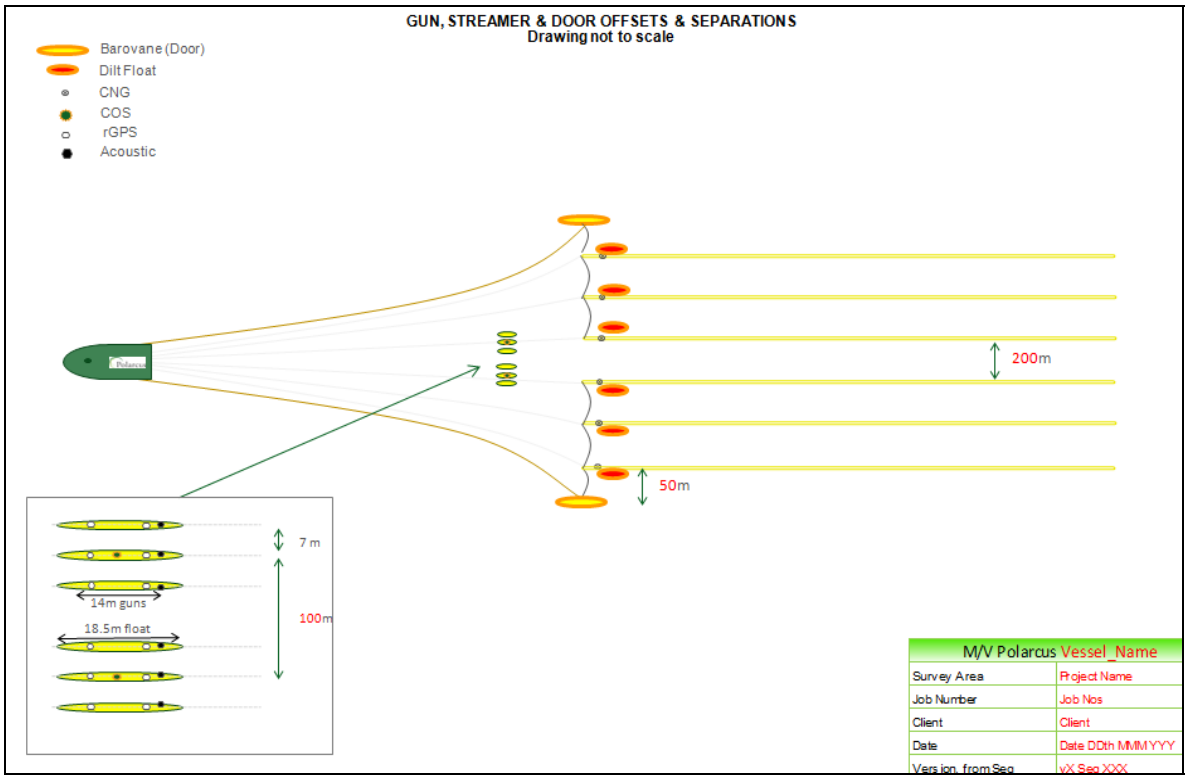

FIGURE 4-6. Schematic overview of preliminary towing geometry of each seismic vessel. CNG = centre of nearest (receiver) group; COS = centre of source; rGPS = relative GPS; Acoustic = acoustic pinger.

4.2.6 Additional Equipment

The seismic vessels will be equipped with a gravity meter and possibly a magnetometer. These are both passive recording devices that do not emit sound. Each of the seismic vessels is equipped with a Furuno FE-700 echosounder. The downward-facing Furuno FE-700 operates at a frequency of 50 kHz or 200 kHz and will be used to collect water depth information.

A pinger system will be used during seismic operations to position the airgun array and hydrophone streamers relative to the vessel. Sounds from the pingers are single code transmission of 256 ms. One pulse is emitted on command from the operator aboard the source vessel, which under normal operating conditions is once every ~8–16 s. Most of the energy in the sound pulses emitted by this pinger is at very high frequencies between 26 and 100 kHz. The signal is omni-directional.

For the 2012 Project, up to 15 sound velocity profiles will be acquired in the water column at various locations within the Seismic Area. This is a routine practice during seismic programs. Sound velocity profiles allow for more accurate interpretation of the acoustic data (i.e., seismic pulses) recorded by the seismic streamers. These data are acquired with a small, passive device that will be deployed by a support vessel. The device measures pressure, temperature, and salinity, from which the speed of sound can be calculated.

4.2.7 Visual and Acoustic Monitoring

Visual Monitoring
Shell will meet or exceed the requirements for MMSOs on each of the seismic vessels. At present, it is planned to place two MMSOs on the *Polarcus Samur*, four MMSOs on the *Polarcus Amani*, and two MMSOs on each of the support vessels. The MMSOs will be tasked with implementing monitoring and mitigation measures as detailed in the Seismic EIA Guidelines (Kyhn et al. 2011) and provided in the Environmental Management Plan (see Section 7). At present there is no intention to have a Fisheries Liaison Officer (FLO) on-board, unless this is required by BMP.

Passive Acoustic Monitoring
Both seismic vessels will implement Passive Acoustic Monitoring or PAM. The PAM system (see Table 4-3) consists of four small omni-directional, high bandwidth hydrophones in conjunction with pre-amplifier units that provide an improved signal to noise ratio. The hydrophones, along with a depth sensor, are contained in a 22.5-m section of cable deployed 200 m behind the seismic vessel. Another option is to deploy the hydrophones in a “mini-array” that can readily be interfaced to the airgun array using airgun array cable returns to the vessel’s instrument room. Operators of the PAM system would monitor two laptop computers, one each for high- and low-frequency analyses. The high-frequency system (employing a National Instruments DAQ card) is used to detect and localize ultrasonic pulses emitted by dolphins and porpoises. The low-frequency system is used to detect sounds produced by cetacean sounds in the 20 Hz–20 kHz range and up to a maximum of 48 kHz for 2 channels and 96 KHz for 1 channel if required. Further details of the PAM system are provided in Section 7.

4.2.8 Logistics

At the time of this submission, final plans for fuel, water, food, personnel transfer, and material supply are not entirely in place. In the preliminary plan, the supply vessel will provide consumables to both seismic vessels and the four chase vessels. It is anticipated that Project vessels will require refuelling every 16–21 days. Refueling will occur within the Project Area. The supply vessel will either acquire fuel from a tanker or the port of Illulisat. Refuelling will follow Polarcus bunkering procedures that have been established based on IMO maritime regulations.

TABLE 4-3. Specifications of PAM system for Shell's 3-D seismic survey (as per Table 6.4.4 required in Seismic EIA Guidelines; Kyhn et al. 2011).

Specify	**Description**	**Provided**
Number of hydrophones	Four small omni-directional high-bandwidth hydrophones	Yes
Threshold of the recording system	SNR-106 dB, Dynamic Range106 dB	Yes
Sample rate of the recording system	Sampling to 96 or 192 Ks/s giving 48–96 kHz	Yes
Where will hydrophones be placed?	In a 22.5-m long streamer towed behind the seismic vessels or in a mini-array interfaced with the airgun array.	Yes
Will there be duty cycling of recordings? In that case, when will the PAM system be used?	No.	Yes
Name of software	Pamguard, Ishmael 1.0, Sigview, PC Scope	Yes
Species covered	Ultrasonic pulses of dolphins, porpoises; vocalizations of mysticetes and odontocetes with frequencies ranging from 20 Hz to 20 kHz; up to 48 kHz in two channels and 96 kHz in one channel.	Yes
Estimated range accuracy, m.	50 m	Yes

Note: SNR = Signal to Noise Ratio.

Crew changes are likely to occur via vessel-to-vessel transfers. Crew changes will take place approximately every six weeks with an anticipated 2–3 crew changes per seismic vessel conducted during the Project. The base for crew changes will be Upernavik.

Each seismic vessel will have a total of ~50 crew members. The crew on the support vessels will be ~8–10 per vessel. Crew change details for the support vessels will only be known once the vessels have been contracted (expected in March).

4.2.9 Emissions, Discharges and Waste Management

Emissions to Air
The primary source of emissions to the atmosphere will be from vessel engines. Vessels will only use diesel and gasoil with a sulphur content of less than 1.5% (weight). It is estimated that the total fuel consumption of seismic vessels during the program will be 9,000 t. For the proposed Project, Polarcus has modelled emissions for the two seismic vessels assuming 8800 km^2 of data acquisition and a production speed of 4.5 knots. CO_2, So_x, and NO_x emissions were predicted as 19,316 tonnes, 3.0 tonnes, and 51.3 tonnes, respectively.

Liquid Discharges
Vessel discharges will not exceed those of standard vessel operations and will adhere as a minimum to appropriate regulations. The main discharges include grey water (wastewater from washing, bathing, laundry, and food preparation) and black water (human wastes from washrooms). All discharges will comply with requirements in the International Convention for the Prevention of Pollution of Ships, 1973, as modified by Protocol of 1978 (MARPOL 73/78) and its annexes. It is estimated that each seismic vessel will generate 5–6 m^3 of black and grey water per day.

Solid Wastes
Polarcus has a Garbage Management Plan in place that meets or exceeds MARPOL requirements (MARPOL 73/78, Annex V). All solid wastes will be sorted by type, compacted where practicable, and stored on board before disposal to an appropriate certified reception facility. Food waste from the seismic vessels will be burned onboard in the DNV approved incinerator. Sufficient and adequate facilities will be available on vessels to store solid wastes to the extent required. All wastes during the survey will be managed in accordance with MARPOL requirements (i.e., Annex IV and Annex V of the MARPOL Convention) and relevant national legislation, with consideration of best environmental practices (see Section 7).

5 DESCRIPTION OF THE ENVIRONMENT

5.1 Recent Assessments and Studies

The Project Area falls entirely within the boundaries of the Baffin Bay assessment area. Therefore, as recommended in the BMP Guidelines (2011), the information in this section refers to the SEIA for the Baffin Bay assessment area where appropriate (Boertmann and Mosbech 2011). Other key studies referenced in this section include Boertmann et al. (2009), Stjernholm et al. (2011), and Fissel et al. (2012).

In addition, as recommended in the Seismic EIA Guidelines (Kyhn et al. 2011), this section focuses on the biological components of the environment that are most likely to interact with the Project, notably marine mammals, fish, invertebrates, and seabirds, as well as commercial fisheries and subsistence harvesting. Seabird and marine mammal data were collected in the Study Area from a geophysical site survey vessel conducted in August–September 2011. The findings of this monitoring program are presented here.

5.2 Environmental Setting Overview

The Project Area occurs on the continental shelf and slope of West Greenland in water depths ranging from ~150 to >2000 m (Figure 4-1). Sections 5.3 to 5.6 provide a general overview of the baseline conditions in the Study Area, focused on the physical, biological, and socioeconomic components that could be affected by Project activities. As noted throughout these sections, there is a better understanding of environmental conditions in nearshore areas than in offshore areas, including the area where Shell is proposing to acquire seismic data.

5.3 Physical Environment

The physical environment in and near the Study Area is summarized here based on a report prepared by ASL Environmental Sciences Inc. (see Appendix B). A review of the physical environment of the larger Baffin Bay assessment area is provided in Section 3 of the SEIA (Boertmann and Mosbech 2011).

5.3.1 Weather

Of particular relevance to this Project are the effects that weather can have on Project operations as well as the ability of MMSOs to effectively monitor marine mammals and seabirds. In general, the Study Area has low wind speeds, precipitation levels, and air temperatures, with foggy conditions during summer.

Air Temperatures
The Study Area has mean air temperatures below 10ºC all year round. Summer (July–September) temperatures over the ocean are usually close to surface water temperatures, which typically range from -1.8ºC to 5ºC (Appendix B).

Winds
The steep coasts of Baffin Bay, with heights exceeding one kilometre, have a substantial impact on winds. Air flows along the steep coasts instead of across them. South easterly and easterly winds prevail along the northern coast of Greenland, and north westerly winds dominate over the open ocean (see Figure 6 in Appendix B). The mean wind velocity in and near the Study Area is ~4 m/s (14.4 km/h). The winds are the strongest and most persistent near the coast. In summer, the winds are generally from the southeast and in winter, the strongest winds blow from the northwest (Valeur et al. 1996). In summer (June–September), the frequency of occurrence of gale force winds was about 0.5% at a monitoring station located within the Study Area (Hansen et al. 2004).

Precipitation
Precipitation measurements, as determined from coastal weather stations at Upernavik and Pituffik (Cappelen 2008), indicate total precipitation levels of about 200 mm/year, which are small by comparison with southern Greenland. The largest monthly values of precipitation occur in late summer and fall with very low levels during the winter and early spring. Most of the precipitation occurs in the form of snow except in summer when rainfall does occur.

Fog
The estimated frequency of occurrence of fog in the open waters of July is ~30% in offshore areas and decreasing nearer the coastline (see Figure 10 in Appendix B). Fog conditions primarily occur because of advection of warm and moist air passing over the cold sea surface resulting from melting sea ice. Occurrences of fog decline later in the summer and in autumn with the reduced presence of sea ice.

5.3.2 Oceanography

The oceanographic conditions in and near the Study Area, including bathymetry, water masses, currents, freshwater inputs, and oceanic fronts are reviewed in Appendix B. Of particular relevance to the Project are wave conditions because of the potential influence on vessel operations.

Because of the moderate wind conditions in Baffin Bay, wave heights are characteristically small, with a 10% probability of exceeding 1.7 m at 72°N and 60°W for the four-month period August–November, 1985–1996 (Valeur et al. 1996). Larger waves can occur, but these are usually of short duration. Waves have minimum levels in the early summer months when considerable amounts of sea ice are present as well as the lower summer winds, whereas larger waves occur in the fall with more open water and higher winds.

5.3.3 Ice Conditions

Sea Ice

Sea ice is an important part of the marine physical environment of Baffin Bay, and can directly affect the Project. The operations are scheduled to avoid typical periods of sea ice cover in the Project Area. Over the past 30 years, the average ice break-up date in the Project Area (Anu and Napu blocks) has been the week of 16 July, and the ice breaks up earlier on 2 July in the northwest Qamut block and even earlier, 18 June–2 July, in the south westerly Tooq block (Figure 20 in Appendix B). The average freeze-up dates over the past 30 years have been well into November, i.e., 19 November in the Project Area. Of note, the average break-up dates over the past 13 years have been about three weeks earlier (in late June) than the 30-year climate normal value. There is also a recent trend toward reduced ice concentrations in the Project Area that persists through the summer months and into early autumn (see Appendix B).

The typical and extreme ice conditions in and near the Study Area over the past 30 years (1981–2010, inclusive) are described in Appendix B. In August, September, and October, sea ice is absent from the Project Area in most years. Sea ice has not been reported in the Project Area in August and September since 1996, with the exception of 2004, when low ice concentrations were observed in the Napu block because of unusually late lingering of the Middle Ice Pack.

Icebergs

In addition to sea ice, icebergs represent an important part of the physical environment of Baffin Bay that can directly affect the Project. Nearly all icebergs in Baffin Bay originate from tidewater ice sheets located in fjords between Disko Bay and Kap York in the northern half of West Greenland, with the most productive ice sheets located in Melville Bay (Figure 26 in Appendix B). Analysis of iceberg distributions in north eastern Greenland (Figure 28 in Appendix B) reveals that the highest densities of iceberg occur north of 75°N and east of 60°W within ~50–100 km of West Greenland, i.e., shoreward of the Project Area.

5.4 Biological Environment

5.4.1 Primary Productivity

Boertmann and Mosbech (2011) reviewed published studies of primary productivity in the Baffin Bay assessment area, and provided a series of maps of satellite-derived estimates of surface chlorophyll concentration. Total primary production in the arctic is from three sources: phytoplankton, ice algae on the underside of fast or drift ice, and benthic algae. In Lancaster Sound, Welch et al. (1992) estimated their contributions at ~90%, 10%, and 1%, respectively.

In most of Baffin Bay, there is a brief and intense phytoplankton bloom immediately after ice break-up, with high transient phytoplankton biomass and relatively low total primary production integrated over depth and season (Boertmann and Mosbech 2011). Exceptions are polynyas, areas of open water surrounded by ice, some of which are recurring and remain open throughout the winter. A notable example in the Baffin Bay assessment area is the North Water Polynya, which is “one of the most biologically productive marine areas in the Arctic” (Boertmann and Mosbech 2011:47). The North Water Polynya is located in Smith Sound, to the north and west of the Study Area (see Figure 4-1).

5.4.2 Zooplankton

Zooplankton provides the main pathway to transfer energy from phytoplankton to consumers at higher trophic levels, e.g., fish, marine mammals, and seabirds, thus has a critical role in marine food webs. High latitude zooplankton production follows the extremely strong seasonal pulse of phytoplankton (Parsons et al. 1984:26). Numerous taxa are included, e.g., chaetognaths, hydrozoans, ctenophores, pteropods molluscs, carnivorous amphipods, and larvaceans, but copepods, particularly calanoid copepods, are dominant. Boertmann and Mosbech (2011) provide additional general information about arctic zooplankton, and also summarize the scant information particular to the Baffin Bay assessment area. Much of that information concerns the North Water Polynya, which is located to the north and west of the Study Area

Studies were carried out near Melville Bay, at 75–76°N, 68–72°W, in summer 1980. The most dominant copepod species are *Calanus hyperboreus*, *C. glacialis*, and *C. finmarchicus*. Their vertical distribution was linked to food availability, salinity, and temperature. The *Calanus* species were most abundant in water with temperatures below <0°C, whereas other species, e.g., pteropods, were most abundant at temperatures >0°C (Boertmann and Mosbech 2011).

5.4.3 Benthic Flora

Studies of the marine benthic flora in the Baffin Bay assessment area are summarized in Boertmann and Mosbech (2011). Benthic flora are primarily found in shallow coastal environments. Whereas a considerable length of West Greenland shoreline occurs in the Study Area, none of it is closer than 60 km to the Project Area. The Project has no potential to affect benthic algae and thus this group is not discussed further here.

5.4.4 Benthic Fauna

Boertmann et al. (2009) indicated that the knowledge of benthic faunal species composition, diversity, and spatial variability in eastern Baffin Bay was limited. In support of the Eastern Baffin Bay SEIA (see Section 4.4 in Boertmann and Mosbech 2011), benthic surveys were conducted in 2008 along 22 inshore transects along the west coast of Greenland between 71°N and 78°N by NERI (now DCE) and GINR, many within the Study Area. Sampling was conducted in four depth ranges: 0–50 m, 50–100 m, 100–150 m, and 150–200 m. Photographs and grab samples were collected.

In photographs, the most abundant benthos were brittle stars (up to several 100/m^2), infaunal bivalves, scallops, and sea urchins. The abundance of large infaunal bivalves was generally highest at 10–50 m depths with a substrate of mixed soft sediment, gravel, and stones. An arctic community characteristic of water depths <50 m, marked by high biomass, the Macoma community, has been recorded in East and West Greenland and the Canadian Arctic, including northwestern Baffin Bay (Vibe 1939; Thorson 1957; Ockelmann 1958; Ellis 1960; Thomson 1982). Included in this community are the bivalves *Macoma calcarea* and *M. moesta*, *Astarte borealis*, *A. montagui*, *Serripes groenlandicus*, and *Mya truncata*, and the polychaete *Pectinaria granulata*.

In grab samples, average biomass was variable among stations (23–1030 g/m^2) and showed no clear relationship with depth or sediment type. Average biomass was ~200 g/m^2 at the three shallower depth ranges and ~175 g/m^2 at 150–200 m depths. Molluscs and polychaetes dominated biomass, whereas polychaetes and amphipods dominated numbers (Section 4.4 in Boertmann and Mosbech 2011).

Water depths in the Project Area range from ~150 to >2000 m, mostly deeper than the depths sampled in the benthic study described in Boertmann and Mosbech (2011). At depths 100–1000 m, polychaetes dominate benthic communities, and total biomass at these deeper areas is typically lower than that at shallow sites (Piepenburg 2005 in Boertmann et al. 2009). On the Spitzbergen shelf at 79°N, biomass decreased from ~40 g/m^2 at 200–300 m to ~5 g/m^2 at 2000 m (Wlodarska-Kowalczuk et al. 2004 *in* Boertmann and Mosbech 2011).

Information on the fish and large invertebrate species in northwest Greenland waters were summarised by Boertmann et al. (2009), Boertmann and Mosbech (2011), and Stjernholm et al. (2011). The first two are SEIAs that cover the Baffin Bay assessment area, covering ~71–80°N, and the third is an oil spill sensitivity atlas that covers the shoreline and the offshore areas between 72°N and 75°N. Other sources of information used here include peer-reviewed literature and technical reports.

5.4.5 Fish (Including Macroinvertebrates)

Macroinvertebrates

Northern shrimp.—The northern shrimp (*Pandalus borealis*) occurs on the West Greenland continental shelf from Cape Farewell at ~60°N to ~74°N (Boertmann and Mosbech 2011). It typically occurs in waters 100–600 m deep, mainly on the outer slopes of banks. Although northern shrimp are considered bottom dwellers, they migrate vertically at night and sometimes during the day to feed on the small planktonic organisms in the upper water column (Rose 2007).

Northern shrimp eggs are extruded in the summer and then carried by the female until the following spring (April–May) when the females move to shallower water (<150 m) where the larvae hatch (Boertmann and Mosbech 2011). The larvae are planktonic for 3–4 months, drifting passively with the currents. They subsequently settle to the ocean floor as far as 500 km from their hatching site (Rose 2007). Shrimp larvae are generally more abundant in waters <200 m deep (Pedersen and Smidt 2000). Important areas for shrimp larval development are the slopes of the banks, on the banks, and the shelf break. By the end of their first year, most northern shrimp have settled to the seafloor as juveniles (Rose 2007).

Snow crab.—The snow crab (*Chionoecetes opilio*) occurs over a broad depth range in the northwest Atlantic from Greenland south to the Gulf of Maine (DFO 2008). Snow crabs are patchily distributed along the west coast of Greenland in coastal areas and fjords, typically at 180–400 m depths (Stjernholm et al. 2011). Large males are most common on mud or mud/sand, whereas smaller crabs are common on harder substrates (DFO 2008). The snow crab life cycle is characterized by larval hatching in the spring, followed by a 12–15 week planktonic period during which the larvae develop through various stages before settling to the sea bottom (DFO 2008). Benthic juveniles of both sexes moult frequently. At ~4 years of age, they become sexually mature.

Iceland scallop.—Iceland scallops are generally found inshore and on banks at 20–60 m depths where current velocity is relatively high (Stjernholm et al. 2011). The West Greenland populations and commercial aggregations of Iceland scallop are generally found in coastal areas (Pedersen 1994). The Iceland scallop lives on the surface of hard substrates, rarely on soft, muddy bottoms (Crawford 1992 *in* Wroblewski et al.2009). In West Greenland, the largest aggregations are found in the Nuuk area, where most of the directed fishery has taken place (Pedersen 1994). In offshore areas there are only low concentrations of generally small scallops and large quantities of empty scallop shells, suggesting that offshore populations were once more abundant than they are currently.

Reproduction is by broadcast spawning, which is cued by rising water temperatures (Arsenault et al. 2000). Pedersen (1994) suggested a peak of spawning in late May–early June. After 6–10 weeks in surface waters, the planktonic larvae settle to hard sand and gravel surfaces (Arsenault et al. 2000).

Fish

Jørgensen et al. (2005 *in* Boertmann and Mosbech 2011) identified seven bottom fish assemblages in bottom trawls conducted in Davis Strait and Baffin Bay in 1999 and 2001. The trawls included the southern portions of the Study Area and Project Area (to 74°N) at depths down to 1500 m. Four of the identified fish assemblages were unique to Baffin Bay. The northern part of Baffin Bay (72–77°) was surveyed by bottom trawl in 2004 at depths 150–1418 m. This survey area included all of the Study Area. Forty-seven species were identified, 42 of them benthic species, with Greenland halibut being the dominant species caught. Other notable species caught in this survey included polar cod and arctic cod and arctic skate (*Raja hyperborea*).

The following species are those considered important between 72°N and 75°N (Stjernholm et al. 2011).

Greenland halibut.—The Greenland halibut is a deep-water, semi-pelagic flatfish that inhabits depths of ~400–2000 m (Rose 2007; Boje and Hareide 1993 *in* Gundersen et al. 2009). It spends most of its life on the bottom, but migrates into the water column to feed (Boertmann and Mosbech 2011). The reproductive biology of Greenland halibut is poorly understood (Gundersen et al.2009). Greenland halibut spawn a large number of pelagic eggs in winter at depths >1000 m and south of 67°N. The eggs and larvae drift northward and the larvae subsequently settle in the shallower waters of the banks. Greenland halibut are an important source of food for narwhals in winter (Boertmann and Mosbech 2011).

Lumpfish.—In the Northwest Atlantic, the lumpfish (or lumpsucker) ranges from Greenland south to Chesapeake Bay (DFO 2006). Lumpfish spend most of the year in deep, offshore waters, but in spring and early summer, typically May–June, they seek shallow coastal waters to spawn. Females lay two to three egg masses at intervals of 8–14 days. Once the eggs are deposited, females migrate back to deeper water leaving the males to guard the egg masses (DFO 2006). Larvae are released after 6–8 weeks of incubation. Juveniles are semi-pelagic, remaining in the top metre of the water column for their first year, during which they are often associated with floating algae. Lumpfish occur only in the southernmost part of the Baffin Bay assessment area (Boertmann and Mosbech 2011). Their northern distribution limit is at 72–75°N, so they are of limited importance there (Stjernholm et al. 2011).

Arctic char.—The arctic char is widespread in Greenland, including the most northerly areas (Muus 1990 *in* Boertmann and Mosbech 2011). Both resident and anadromous populations of arctic char occur there. Resident populations spend their entire lives in lakes and rivers, whereas anadromous populations migrate to the sea in summer to feed, and move back to freshwater in autumn to spawn and winter. Migratory char form an important resource for local consumption in Greenland (Riget and Böcher 1998 *in* Boertmann and Mosbech 2011). At sea, arctic char mainly stay in coastal areas, not far (up to ~25 km) from their natal river (Muus 1990 *in* Boertmann and Mosbech 2011).

Spotted wolffish.—The spotted wolffish occurs in the Arctic Ocean and on both sides of the North Atlantic from Labrador to the Barents Sea (DFO 2009). Off West Greenland, it is found as far north as Upernavik Fjord, and sporadically to Thule (FAO 2009). It is found offshore in cold, deep water, usually <5°C at 50–800 m depths (Kulka et al. 2007). Wolffish prefer a coarse sand and sand/shell hash bottom with rocky areas nearby for shelter, nest building, and spawning (Kulka et al. 2007). Reproduction occurs from April to December, mainly in June–August (FAO 2009). Large eggs are laid in deep water on the sea floor and are guarded primarily by males (DFO 2009). The larvae typically settle to the bottom when a body length of 4–7 cm is attained (FAO 2009). The species does not form large schools and migrations are local and limited (DFO 2009).

Polar cod.—The polar cod (*Boreogadus saida*), known elsewhere as arctic cod, is a pelagic or semi-pelagic species with a circumpolar arctic distribution. It can form large aggregations, often deep in the water column or near the bottom on the shelf (Boertmann and Mosbech 2011). It also occurs in coastal waters and is often associated with sea ice, in crevices and holes in the ice. Polar cod spawn large buoyant eggs in ice-covered waters in November–February, and the eggs incubate under the ice until larvae hatch in late spring when the ice starts to melt (Boertmann and Mosbech 2011).

The polar cod is an important forage species in the arctic marine food web. It is a key prey for many marine mammals and seabird species, especially the ringed seal, harp seal, beluga, narwhal, thick-billed murre, northern fulmar, black-legged kittiwake, and gulls (Boertmann and Mosbech 2011).

Capelin.—The capelin is a small, pelagic, schooling fish. It is a cold-water species that occurs widely in the northern Hemisphere. In the Disko Bay area, capelin spawn in huge numbers in spring in the subtidal zone along beaches and low rocky coasts (Mosbech et al. 2007). Capelin occur only in the southernmost part of the Baffin Bay assessment area (Boertmann and Mosbech 2011). Their northern distribution limit is at 72–75°N, so they are of limited importance there (Stjernholm et al. 2011).

5.4.5 Birds

Project activities, and thus expected potential impacts on birds, are primarily offshore and occur during the open-water season. Therefore, the following description focuses on the offshore avifauna during the July–October period. The avifauna of the offshore is less diverse than that of the nearshore/coastal waters of western Greenland. Two sources provided most of the information for this review: the recently released SEIA for the Baffin Bay Assessment Area (Boertmann and Mosbech 2011) and the report on marine mammal and seabird surveys conducted during a seismic site survey, 11 August–18 September 2011 (Abgrall and Harris 2011). Boertmann and Mosbech (2011) provided much useful information on the distribution, abundance, nesting, and ecology of coastal, nearshore, and offshore birds of the region. Information more specific to Shell's Project Area is provided in Abgrall and Harris (2011). The 2011 seismic site survey report includes seabird observations from 65–76°N, including areas well south of the areas of interest for 2012. The following discussion focuses on those observations made within the areas of interest for 2012, approximately 72–76°N. Whereas there is a good general understanding of the species, nesting concentrations, coastal occurrence, and general ecology of the avifauna of eastern Baffin Bay, data on the offshore occurrence of birds is limited.

During the open-water season, eastern Baffin Bay hosts a rich seabird community because of its combination of rich marine feeding areas and nearby suitable cliff-nesting habitat. Many seabirds nest in numerous colonies along the coast of northwest Greenland. Approximately 80% of the world's population of little auk nests along cliffs there: an estimated 33 million pairs. Northwest Greenland also supports the vast majority of Greenland's nesting thick-billed murres. Overall, the area supports birds during the spring and fall migrations, and for nesting, brood-rearing, moulting, and staging. Birds migrate to eastern Baffin Bay from the eastern Canadian Arctic, eastern Canada and northeastern United States, western Europe, and the south Atlantic. In total, it is estimated that at least one hundred million seabirds (adults and juveniles combined) move through Baffin Bay during September and October. Many of those are flightless adult and juvenile thick-billed murres on a swimming migration.

The most abundant species observed offshore during the 2011 seismic site survey were the northern fulmar, black-legged kittiwake, glaucous gull, thick-billed murre, and little auk (Abgrall and Harris 2011). Most of those are true pelagic seabirds, and all nest abundantly along the coast of northwest Greenland. Other species recorded less commonly offshore were the common eider, red phalarope, jaegers (pomarine, parasitic, and long-tailed), ivory gull, Iceland gull, arctic tern, and black guillemot. Table 5-1 summarizes the occurrence of birds recorded in and near the 2012 Project Area during the 2011 seismic site survey.

Table 5-2 presents the densities of on-transect sightings. During the 2011 seismic site survey, in areas north of 72°N, on-transect densities for all birds combined ranged from 1.96 birds/km^2 (August, latitudes 72–74°N) to 9.11 birds/km^2 (September, latitudes 74–76°N) (Table 5-2). The northern fulmar, black-legged kittiwake, glaucous gull, thick-billed murre, and little auk accounted for most of the on-transect sightings.

Populations of several species known to occur in the Project Area are on the Greenland Red List, and/or are otherwise of national or international importance. Table 5-3 presents the conservation status of these species (adapted from Table 3 *in* Boertmann and Mosbech 2011).

Shell in the Arctic

DEFINITIONS AND CAUTIONARY NOTE

Reserves: Our use of the term "reserves" in this presentation means SEC proved oil and gas reserves for all 2009 and 2010 data, and includes both SEC proved oil and gas reserves and SEC proven mining reserves for 2008 data.
Resources: Our use of the term "resources" in this presentation includes quantities of oil and gas not yet classified as SEC proved oil and gas reserves or SEC proven mining reserves. Resources are consistent with the Society of Petroleum Engineers 2P and 2C definitions.
Organic: Our use of the term Organic includes SEC proved oil and gas reserves and SEC proven mining reserves (for 2008) excluding changes resulting from acquisitions, divestments and year-acerage pricing impact.

To facilitate a better understanding of underlying business performance, the financial results are also presented on an estimated current cost of supplies (CCS) basis as applied for the Oil Products and Chemicals segment earnings. Earnings on an estimated current cost of supplies basis provides useful information concerning the effect of changes in the cost of supplies on Royal Dutch Shell's results of operations and is a measure to manage the performance of the Oil Products and Chemicals segments but is not a measure of financial performance under IFRS.

The companies in which Royal Dutch Shell plc directly and indirectly owns investments are separate entities. In this presentation "Shell", "Shell group" and "Royal Dutch Shell" are sometimes used for convenience where references are made to Royal Dutch Shell plc and its subsidiaries in general. Likewise, the words "we", "us" and "our" are also used to refer to subsidiaries in general or to those who work for them. These expressions are also used where no useful purpose is served by identifying the particular company or companies. ''Subsidiaries'', "Shell subsidiaries" and "Shell companies" as used in this presentation refer to companies in which Royal Dutch Shell either directly or indirectly has control, by having either a majority of the voting rights or the right to exercise a controlling influence. The companies in which Shell has significant influence but not control are referred to as "associated companies" or "associates" and companies in which Shell has joint control are referred to as "jointly controlled entities". In this presentation, associates and jointly controlled entities are also referred to as "equity-accounted investments". The term "Shell interest" is used for convenience to indicate the direct and/or indirect (for example, through our 24% shareholding in Woodside Petroleum Ltd.) ownership interest held by Shell in a venture, partnership or company, after exclusion of all third-party interest.

This presentation contains forward-looking statements concerning the financial condition, results of operations and businesses of Royal Dutch Shell. All statements other than statements of historical fact are, or may be deemed to be, forward-looking statements. Forward-looking statements are statements of future expectations that are based on management's current expectations and assumptions and involve known and unknown risks and uncertainties that could cause actual results, performance or events to differ materially from those expressed or implied in these statements. Forward-looking statements include, among other things, statements concerning the potential exposure of Royal Dutch Shell to market risks and statements expressing management's expectations, beliefs, estimates, forecasts, projections and assumptions. These forward-looking statements are identified by their use of terms and phrases such as ''anticipate'', ''believe'', ''could'', ''estimate'', ''expect'', ''intend'', ''may'', ''plan'', ''objectives'', ''outlook'', ''probably'', ''project'', ''will'', ''seek'', ''target'', ''risks'', ''goals'', ''should'' and similar terms and phrases. There are a number of factors that could affect the future operations of Royal Dutch Shell and could cause those results to differ materially from those expressed in the forward-looking statements included in this presentation, including (without limitation): (a) price fluctuations in crude oil and natural gas; (b) changes in demand for the Shell's products; (c) currency fluctuations; (d) drilling and production results; (e) reserve estimates; (f) loss of market share and industry competition; (g) environmental and physical risks; (h) risks associated with the identification of suitable potential acquisition properties and targets, and successful negotiation and completion of such transactions; (i) the risk of doing business in developing countries and countries subject to international sanctions; (j) legislative, fiscal and regulatory developments including potential litigation and regulatory measures as a result of climate changes; (k) economic and financial market conditions in various countries and regions; (l) political risks, including the risks of expropriation and renegotiation of the terms of contracts with governmental entities, delays or advancements in the approval of projects and delays in the reimbursement for shared costs; and (m) changes in trading conditions. All forward-looking statements contained in this presentation are expressly qualified in their entirety by the cautionary statements contained or referred to in this section. Readers should not place undue reliance on forward-looking statements. Additional factors that may affect future results are contained in Royal Dutch Shell's 20-F for the year ended 31 December, 2010 (available at www.shell.com/investor and www.sec.gov). These factors also should be considered by the reader. Each forward-looking statement speaks only as of the date of this presentation, 26 June 2012. Neither Royal Dutch Shell nor any of its subsidiaries undertake any obligation to publicly update or revise any forward-looking statement as a result of new information, future events or other information. In light of these risks, results could differ materially from those stated, implied or inferred from the forward-looking statements contained in this presentation. There can be no assurance that dividend payments will match or exceed those set out in this presentation in the future, or that they will be made at all.

The United States Securities and Exchange Commission (SEC) permits oil and gas companies, in their filings with the SEC, to disclose only proved reserves that a company has demonstrated by actual production or conclusive formation tests to be economically and legally producible under existing economic and operating conditions. We use certain terms in this presentation, such as resources and oil in place, that SEC's guidelines strictly prohibit us from including in filings with the SEC. U.S. Investors are urged to consider closely the disclosure in our Form 20-F, File No 1-32575, available on the SEC website www.sec.gov. You can also obtain these forms from the SEC by calling 1-800-SEC-0330.

Dealing with common Myths

- Arctic oil and gas is not needed
- Gold rush for Arctic oil
- Climate Change enables oil exploration
- Pristine and undeveloped region
- No infrastructure to support operations
- Inadequate science of ecosystem
- Darkness / high seas and ice cover
- High Risks - Fiscal / Technical / Societal
- Inevitable Oil Spills - "Arctic Macondo"
- Lack of Industry Oil Spill Prevention and Response capability and limited R&D

The global energy future to 2050

Rising Energy Demand	Supply Pressure	Climate Change

9 billion people; 75% living in cities
2 billion more than today

3-4 times as rich as today
as population in developing countries shifts from poverty to middle class

2 billion vehicles
800 million at the moment

50% more energy
supplying about 50% more energy than today in 2050. At the same time having to reduce CO_2 and GHG emissions

Half the energy intensity
using half the energy as now to produce each dollar of wealth

3 times today's renewables
energy from renewable sources will be 3 times as much as it is today

1. INTRODUCTION

Shell Greenland A/S (hereafter Shell) is the operator of the license blocks 5 (Anu) and 8 (Napu) in Baffin Bay, Greenland (Figure 1-1).

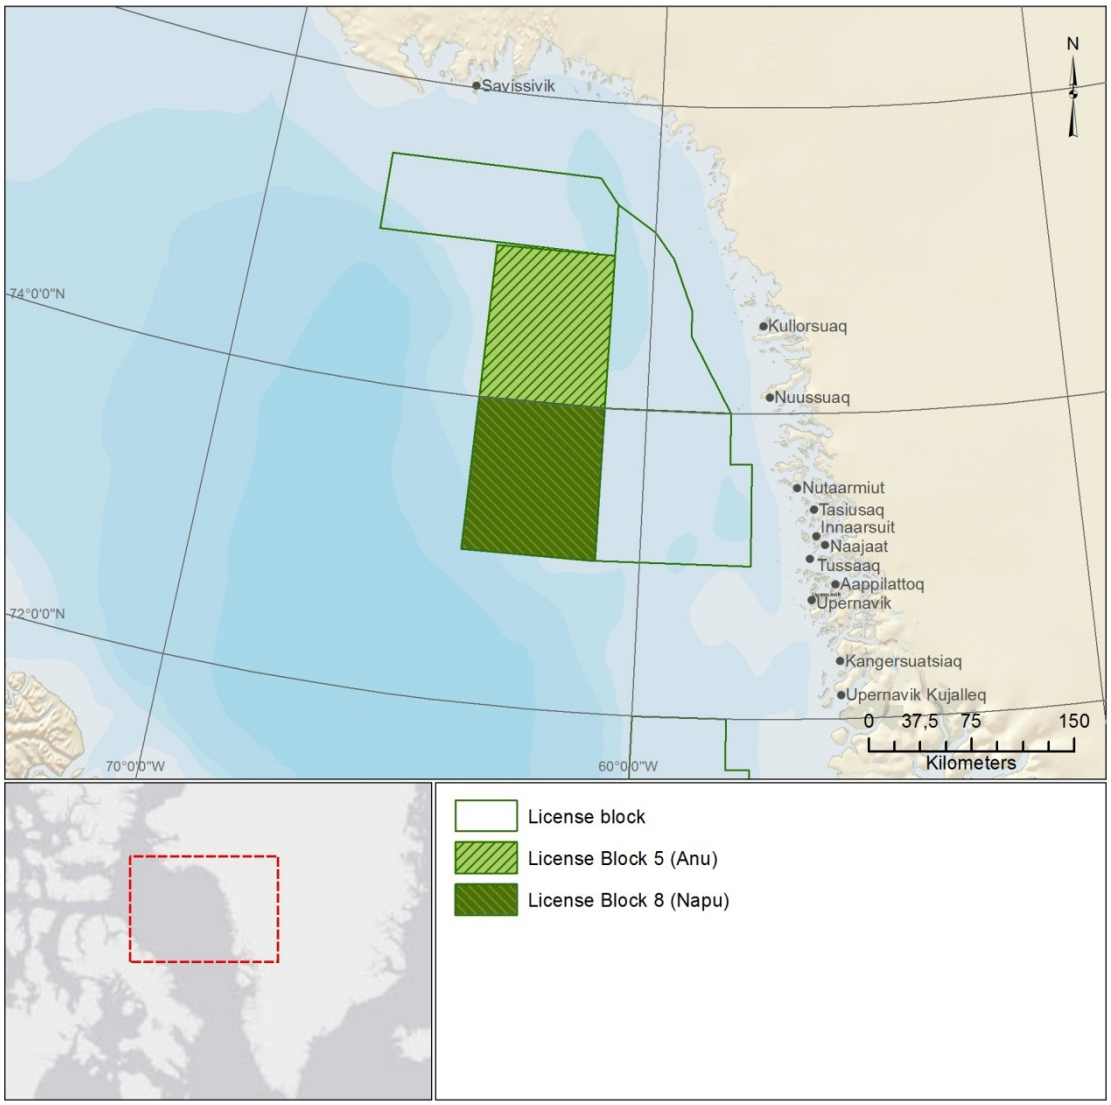

Figure 1-1 Location of the license blocks Anu (Block 5) and Napu (Block 8) in Baffin Bay, Greenland.

The two license blocks each cover an area of approximately 10,000 km^2. The licensees are the same for the two license blocks. In addition to Shell (the operator), the licensees are GDF SUEZ E&P Greenland AS, Statoil Greenland A/S and NUNAOIL A/S. License numbers for the two blocks are No. 2011/12 and No. 2011/14.

1.1 Exploration activities

To date, Shell has been the operator for a Site Hazards Survey (2011), a Shallow Coring Project (2012) and a 3D Seismic Survey (2012). Based on these, potential sites for exploratory drilling have been identified.

In 2013, Shell is planning to conduct a site survey of the potential drilling sites. The proposed 2013 activities are described in section 3.

1.2 Environmental impact assessment

Under the Greenlandic Mineral Resources Act, part 15, exploration-related activities require the submission of an Environmental Impact Assessment (EIA) or, if the activities are not expected of having adverse effect, an Environmental Mitigation Assessment /1/.

Preparation of an Environmental Impact Assessment (EIA) is a systematic process to identify, predict, evaluate and mitigate the environmental impacts of a proposed project, ensuring informed decision-making by the company and the authorities, in this case, the Bureau of Minerals and Petroleum (BMP).

This environmental impact assessment (EIA) for the 2013 site survey in Baffin Bay, has been prepared in accordance with a number of environmental acts, guidelines and manuals /1//2//3//4/.

The EIA presents the technical project, stating how the site survey will be conducted, in accordance with Best Available Technique (BAT) and Best Environmental Practice (BEP).
The impact assessment addresses a number of physical, chemical, biological and socioeconomic parameters. For each parameter, a description of existing conditions and an impact assessment is presented. For any expected, adverse impacts, mitigating measures will be evaluated and any residual impact will be further assessed. The findings of the EIA provide the basis for an Environmental Management Plan for the survey.

The preliminary EIA will be published by the BMP for public consultation. Answers to submissions will be coordinated by the BMP and published with the final EIA report. The process of the EIA and public consultation is summarised in Table 1-1.

Table 1-1 Time table for the EIA process

Activity	Expected timing
Preliminary EIA submitted to BMP	March 1st 2013
Public consultation	March 1st – April 26th 2013
Response to public and regulatory comments	Expected May 2013
Final EIA submitted	Expected June 2013

2. REGULATORY FRAMEWORK

2.1 Greenlandic legislation and guidelines

The 2013 site survey in Baffin Bay is an activity under the Greenland Parliament Act no. 7, 2009 on mineral resources and mineral resources activities (The Mineral Resources Act) /1/. An amendment to the Mineral Resources Act was adopted by Parliament and in effect by 1 January 2013.

The EIA has been prepared in accordance with Guidelines to environmental impact assessment of seismic activities in Greenland waters, December 2011 /3/ and Manual for seabird and marine mammal survey on seismic vessels in Greenland, May 2012 /4/.

2.2 International treaties, conventions and best practice

Greenland is a self-governing province of Denmark with extensive autonomy on matters of environment and biodiversity. Since the establishment of the home rule in 1979, Greenland has signed a number of international agreements and has undertaken obligations under several international conventions concerning the use, administration and protection of the environment.

As required by the BMP guidelines, offshore exploration activities are planned and executed in a way so that environmental risks are identified, assessed and reduced as much as reasonable practical. Best Available Technique (BAT) and Best Environmental Practice (BEP) shall be applied and used in order to minimise environmental impacts of the site survey. BAT and BEP guidelines (e.g. NORSOK and OGP standards), international conventions (e.g. OSPAR and MARPOL) have been observed in the preparation of the EIA and EMP.

2.3 Shell standards

Shell requires that EIAs are prepared in line with internationally recognised standards. International Finance Corporation Performance Standard 1 is used as a reference document, with Greenlandic requirements and guidelines taking priority.

The site survey will be conducted within the framework of Shell's internal standards and business principles, as well as the environmental, health, and safety policies and procedures of engaged contractors. Environmental, Health and Safety management of the site survey will follow the procedures and requirements as described in Shell's HSSE & SP Control Framework and Corporate Standards (Table 2-1).

Table 2-1 Shell commitment and policy on health, security, safety, environment and social performance.

Commitment	Policy
Shell is committed to: • Pursue the goal of no harm to people • Protect the environment • Use material and energy efficiently to provide our products and services • Respect our neighbours and contribute to the societies in which we operate • Develop energy resources, products and services consistent with these aims • Publicly report on our performance • Play a leading role in promoting best practice in our industries • Manage HSSE & SP matters as any other critical business activity • Promote a culture in which all Shell employees share this commitment	Every Shell Company: • Has a systematic approach to HSSE & SP management designed to ensure compliance with the law and to achieve continuous performance improvement • Sets targets for improvement and measures, appraises and reports performance • Requires contractors to manage HSSE & SP in line with this policy • Requires joint ventures under its operational control to apply this policy, and uses its influence to promote it in its other ventures • Engages effectively with neighbours and impacted communities • Includes HSSE & SP performance in the appraisal of staff and rewards accordingly.

3. PROJECT DESCRIPTION

3.1 Project overview

Shell, as operator, is planning to undertake a site survey during the summer season of 2013 as preparation for future exploration of the license blocks 5 and 8 in Baffin Bay. The 2013 site survey is expected to be carried out by one or two vessels and includes:

- A two-dimensional high resolution (2D HR) seismic survey in multiple survey sites (of app. 3 x 3 km)
- An Environmental Baseline Survey (EBS) in multiple survey sites (of app. 3 x 3 km)
- Service of metocean buoys deployed during the 2011 survey and serviced in 2012
- Deployment and recovery of Passive Acoustic Monitoring (PAM) buoys

The general objective of the site survey is to evaluate the presence of subsurface hazards, such as shallow gas pockets, and to obtain physical, chemical and biological characterisation of the immediate area around the potential drilling sites. The metocean monitoring activities are performed to gain a better understanding of the site-specific meteorological, oceanographic and ice conditions.

Key figures concerning the proposed 2013 survey especially in relation to the seismic activities are presented in Table 3-1 and compared to the 2012 survey in the same area.

Table 3-1 Key figures concerning the 2012 and 2013 surveys

	2012 survey	Proposed 2013 survey
Seismic survey area	~ 8,500 km^2	~ 90 km^2
Duration of seismic activities	~ 2.5 months	~ 10 days
Number of vessels	2 seismic (+ 5 support vessels)	1 seismic (+ possibly 1 EBS)
Size of air gun array	2 x 3,480 in^3	1 x 160 in^3

The following sections provide, in accordance with BMP's EIA Guidelines /3/, a description of the proposed type of work, area, schedule, equipment and materials for the planned 2013 site survey. Table 3-2, Table 3-4, Table 3-3 and Table 3-5 presents survey details in the format required by the BMP EIA Guidelines.

The locations and actual number of survey sites (possibly up to 10 survey sites) are not fixed at this stage. However, the survey sites will be within the three survey areas illustrated in Figure 3-1. The figure also illustrates locations of proposed metocean and PAM buoys. Actual number and exact location of survey sites and metocean and PAM buoys will be determined and communicated to BMP. It is expected that location of survey sites will be situated in the survey areas within the two license blocks. The surveys will be restricted to up to ten survey sites (each 3x3 km) and will occur at depths of 500 – 800 m.

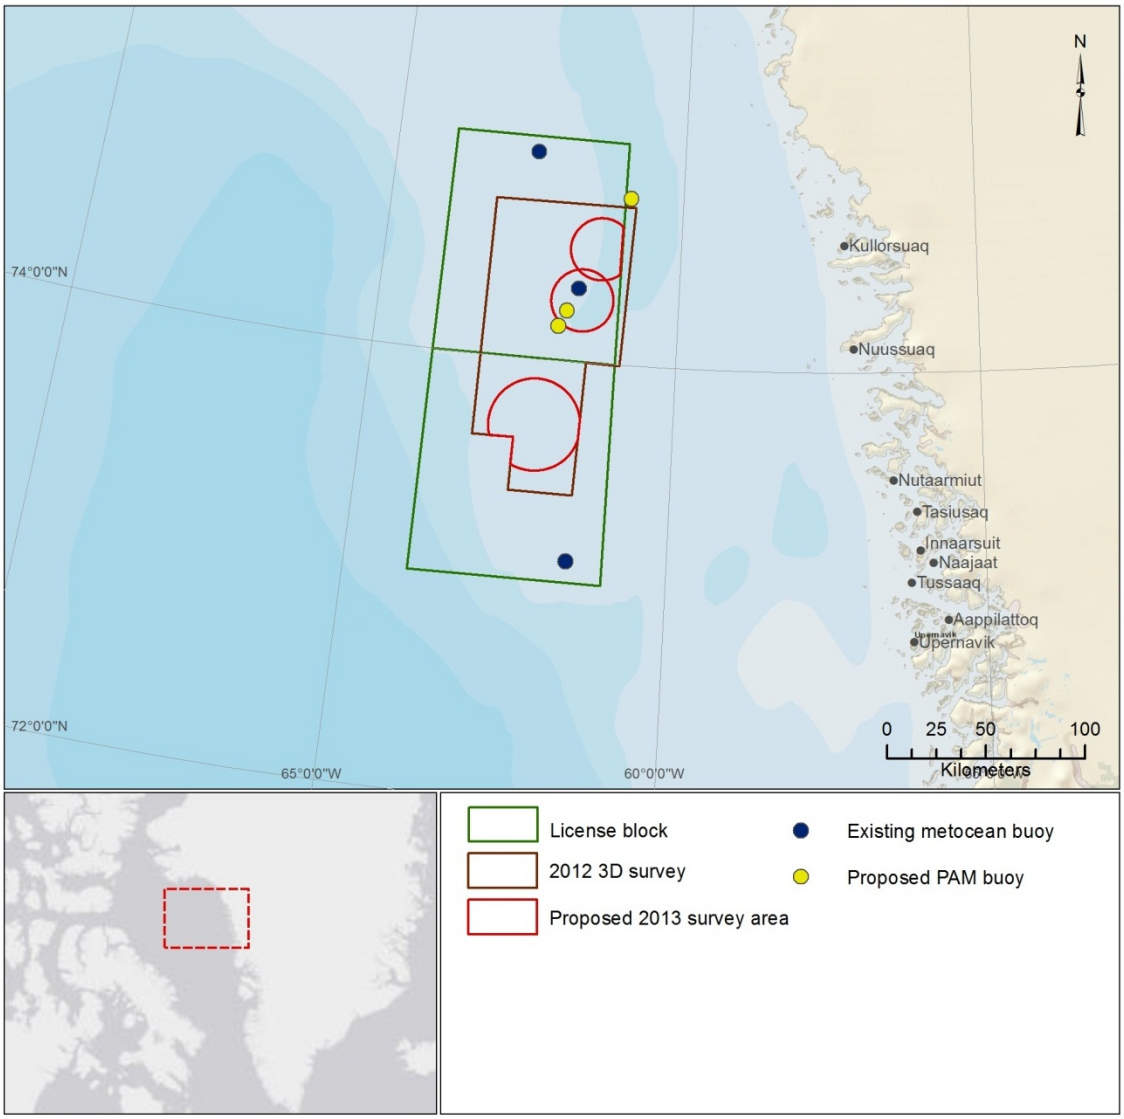

Figure 3-1 Proposed survey areas, locations of metocean buoys and PAM equipment

As illustrated in Figure 3-1 the 2D HR seismic survey is proposed within selected parts of the area covered by the 3D seismic survey conducted in 2012. The area to be covered by 2D HR seismic activities in the proposed 2013 survey is up to 90 km^2. As a reference it can be informed that the 3D seismic survey in 2012 covered approximately 8,500 km^2.

The planned site survey has been announced for tender as of December 19th 2012 and the proposals by potential contractors are requested on February 8th 2013. Award is expected mid-March. Therefore, specific details concerning e.g. vessels (expected up to two), equipment, logistic details etc. cannot be provided in this EIA.

As basis for the assessments in this EIA (see section 5), this section will build on relevant requirements specified to potential providers of this service. Furthermore, descriptions of typical and/or expected equipment for these types of surveys will be described based on experiences from surveys performed under the same licenses in 2011 and 2012 /5//6/.

3.2 Survey schedule and programme

3.2.1 General details

The timing of the site survey is highly dependent on ice conditions. The site survey is proposed to be undertaken in the period between July 15th and October 15th 2013 or as long as prevailing weather/ ice conditions allows. No 2D HR seismic shots will however be performed before August 1st 2013. Survey operations can normally continue 24 hours a day, seven days a week. See also section 3.3.3 and Appendix 2 concerning acoustic monitoring.

The speed and progress of the site survey is likely to be influenced by the weather and the presence of ice in the survey areas. The order of surveyed sites will for the same reason depend on weather and ice conditions and operational requirements.

3.2.2 2D High resolution seismic survey

The site survey includes a 2D HR seismic survey in up to ten 3 x 3 km survey sites within the survey areas in the two license blocks. The line spacing within the 3 x 3 km sites will be 100 m in main line direction with cross lines every 250 m adding up to approximately 135 km survey lines in total for each survey site. The target depth for the survey is maximum 1000 m below seabed.

With an assumed vessel speed of 4 knots the 2D HR seismic surveying is expected to be completed within approximately 24 hours at each survey site. In addition, tie lines to adjacent locations may be required. The specific line orientation within the survey sites will be specified at a later stage of the planning and is not considered of importance to this EIA.

The expected duration of the 2D HR seismic survey will involve the following operations and estimated time requirements within the time window for the planned site survey (August 1st to October 15th 2013):

- Mobilisation and transit to survey area – 7 days
- Survey operation, including transit between sites – 22 days
- Standby (weather downtime) – 4 days
- Demobilisation and transit - 4 days

Table 3-2 provides the survey data requested in the BMP EIA Guidelines for seismic activities in Greenland waters /3/.

Table 3-2 Survey data table

Specify	Description	Provided
Type of survey	2D HR seismic survey and EBS	Shell
Map of the area with all transect lines shown	See Figure 3-1 for survey areas. Specific survey sites (up to 10) are not yet defined Individual survey site sizes are 3 km x 3 km Line density 100 m / 250 m Transect lines not available yet	Shell
Start and end dates for the survey	Earliest start (mobilisation etc.): 15/07/2013 No 2D HR seismic shot before: 01/08/2013	Shell
Expected duration	See section 3.2.2	Shell
Duty cycle of operation (in hours / 24 hours). Number of hours in the dark per 24 hours	24 Hours, see section 3.3.3 concerning use of PAM / Hours of darkness in August: 0 h; September: 8 h; 1-15 October: 12 h	Shell
Number and types of accompanying vessels	No accompanying vessels are expected	Shell
Intended use of icebreakers Will survey be carried out in ice?	Icebreaker assistance is not expected, see section 3.4.	Shell

3.2.3 Environmental baseline survey

Environmental baseline survey (EBS) is proposed at the same sites as the 2D HR seismic surveys (see Figure 3-1) to obtain a physical, chemical and biological characterization of the sites. The EBS work consists of:

- An integrated bathymetry survey by Multibeam Echo Sounder (MBES) and Side Scan Sonar (SSS)
- Visual seabed inspections by Remotely Operated Vehicle (ROV)
- Benthic and sediment sampling by ROV or box corer and/or grab sampler

The expected duration of EBS will involve the following operations and estimated time requirements within the time window for the planned site survey (July 15th to October 15th 2013):

- Mobilisation and transit to survey area – 6 days
- Survey operations, including transit between sites – 51 days
- Standby (weather downtime) – 6 days
- Maintenance – 4 days
- Demobilisation and transit - 4 days

3.2.4 Metocean buoys maintenance

Metocean buoys were deployed in 2011. The buoys were serviced during the 2012 surveys and needs servicing again in 2013. These buoys will be retrieved, serviced and returned to the water. This activity will be carried out as part of the 2D HR seismic survey or the EBS within the time frames for the vessel conducting these services (see section 3.2.2 and 3.2.3).

3.2.5 Passive acoustic monitoring buoys

Deployment and recovery of Passive Acoustic Monitoring (PAM) buoys for recording acoustic output from seismic programme and recording marine mammal vocalizations. These activities will be conducted as part of the 2D HR seismic survey or the EBS within the time frames for the vessel conducting these services (see section 3.2.2 and 3.2.3).

3.3 Type and intensity of activities

3.3.1 BAT and BEP implementation

The survey vessels and equipment for the survey will be selected based on operational requirements and the environment in which the survey is being carried out, e.g. ice class of vessels and minimum size of airgun array used. The vessels and equipment used for the survey will comply with industry Best Available Techniques (BAT) and Best Environmental Practice (BEP).

BAT and BEP will be applied and used during the survey in order to minimise environmental impacts. Mitigation measures required to reduce the level of potential impacts in accordance with BAT and BEP are described in the specific impact sections.

3.3.2 Survey vessels

It is not known at the moment if the 2D HR seismic survey and the EBS will be performed from one or two vessels. Vessels will comply with conventions, laws, regulations and legal requirements that apply to the specific activities in this area.

Marine Mammal and Seabird Observers (MMSOs) will be on the vessel during the site survey, addressing mitigation of potential disturbance to marine mammals. The MMSOs will be tasked with implementing monitoring and mitigation measures as detailed in guidelines to environmental impact assessment of seismic activities in Greenland waters /3/ and in accordance with the DCE Manual for seabird and marine mammal survey on seismic vessels in Greenland, May 2012 /4/. The monitoring may be initiated outside Greenland waters, during vessel transit.

The MMSOs have two tasks.

- To watch systematically for marine mammals before start-up and during seismic survey in order to mitigate and observe safety distances to whales and seals.
- To collect data on abundance and distribution of seabirds and marine mammals through systematic surveys. This task shall be carried out both during times when seismic survey is conducted, and when sailing in transit.

During survey activities in conditions with poor visibility a Passive Acoustic Monitoring (PAM) system will be used on board the vessel. The system is expected to be running during the entire survey to continuously monitor the environment. The PAM system will be operated on board the survey vessel. Detected sounds are processed using specialized software. The MMSOs will be competent in operating the PAM system and interpret the detected sounds.

Details of the PAM system in Table 3-3 are requested in the EIA guidelines. These details will be available at contract award.

Table 3-3 Specifications of PAM system, will be available at contract award

Specify	Description	Provided
Number of hydrophones		
Threshold of the recording system		
Sample rate of the recording system		
Where will hydrophones be placed?		
Will there be duty cycling of recordings? In that case when will the PAM system be used?		
Name of software		
Species covered		
Estimated range accuracy, m.		

Furthermore, a Fisheries Liaison Officer (FLO) will be used if required by BMP to communicate and advise in matters related to the fishery. Refer to section 5.13 concerning fishery.

3.3.3 2D HR seismic survey equipment

The survey vessel for the 2D HR seismic survey will be capable of undertaking the following survey operations in water depths of up to 1,000 meters:

- Shallow seismic geohazard surveys
- Bathymetry surveys (single beam echo sounder)

The survey vessel will deploy the following equipment:

- Single Beam Echo Sounder
- Seismic source for geohazard surveys
- Streamer (solid or gel filled)

In addition to BMP requirements, all survey operations will as a minimum comply with the 2011 OGP Guidelines for the conduct of offshore drilling hazard site surveys /7/. Specifically regarding the offshore seismic survey, the contractor will meet “IAGC Environmental Guidelines for World-wide Geophysical Operations (2001)” and “IAGC Recommended Mitigation Measures for Cetaceans during Geophysical Operations (2009)”.

The contractor for the site survey has not been selected and no specific details on e.g. vessels can currently be provided. Figure 3-2 illustrates a typical 2D HR Seismic site survey. A small air gun (standard source configuration and volumes are expected for this survey) will provide the seismic source, with a 600 m solid or gel filled hydrophone streamer to record the seismic reflection towed behind the survey vessel.

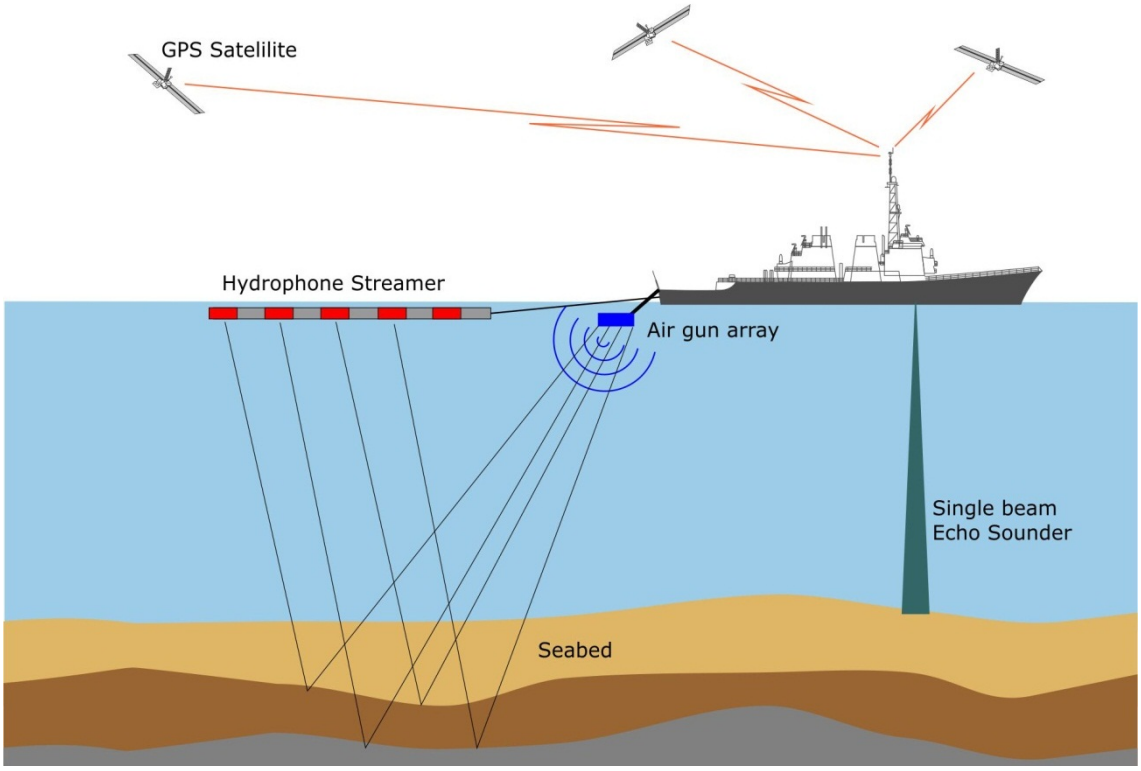

Figure 3-2 Schematic illustration of a typical 2D HR seismic survey setup.

Air guns produce, specifically sound at low frequencies (50-250 Hz) by venting high-pressure air into the water. This produces an air-filled cavity that expands rapidly, then contracts and re-expands to generate the pulsed signal which penetrates the subsurface and is reflected back to the streamers. A single beam echo sounder (SBES) will also be used during the 2D HR seismic survey to obtain knowledge of the seabed. A frequency of 210 kHz is expected for the SBES.

Table 3-4 and Table 3-5 provide the array specifications and acoustic properties of the airgun array requested in the EIA Guidelines for seismic activities in Greenland waters /3/. The presented data pertains to the acoustic modelling performed for this survey, Appendix 2.

For reference it can be informed that the 3D seismic survey conducted in 2012 in the same area was performed using 2 vessels each with an air gun array size of 3,480 in^3 and 6 streamers of 7 km each and supported by 4 chase vessels and 1 support vessel (this 2013 survey assumes an air gun array of 160 in^3, see Table 3-4).

Table 3-4 Array specifications

Specify	Description	Provided
Number and names of vessels towing airgun arrays	One or two vessel will be used for 2D HR seismic survey and EBS. No contracted operator yet.	Shell
For each vessel provide geometric layout of complete airgun array with individual volume specified (in PSI per airgun and in^3 per airgun)	Not available yet. Source configuration and volumes however expected to be standard for 2D HR: 4 x 40 in^3 sleeve gun array.	Shell
Size of total array (In^3 and PSI for the entire array)	160 in^3 is expected	Shell
Firing rate in shots/sec Will sub arrays fire simultaneously or alternate?	Shot point interval 6.25 m at 4 knots.	Shell
Operation speed of the vessel in km/hours or knots.	4 knots	Shell

Table 3-5 Acoustic properties of the airgun array

Specify	Description	Provided
Far field pressure signature (provide figure) **Frequency spectrum of the far field signature (broadband) (provide figure)**	See acoustic modelling report (Appendix 2)	DHI
Source level (source factor) of airgun array on acoustic axis below array, given in all of the following units:		
• **dB re 1 µPa zero- peak (broadband)**	230 dB re µPa	DHI
• **dB re 1 µPa peak- peak (broadband)**	236 dB re 1µPa	DHI
• **dB re 1 µPa rms (Over 90%* pulse dura-tion) (provide duration for rms calculation)**	50 ms pulse duration; 227 dB re 1 µPa	DHI
• **dB re: 1 µPa2s. per pulse**	214 dB re 1 $\mu Pa^2 \cdot s$	DHI
• **Energy, joule/m2 per airgun pulse**	Will be available following contract award	
Signal duration. (Define how it is measured)	50 ms; taken from literature	DHI
Map showing modelled sound pressure levels (rms*), peak-peak and sound exposure level (µPa2s) for the survey area and surroundings (to levels likely to affect marine mammals or nearest land)	See noise maps in acoustic modelling report (Appendix 2)	DHI
Provide description of the noise propagation model, including assumptions of sound speed profiles.	Parabolic Equation RAMgeo code, Sound Speed Profile taken from measurements done in 2012 (details; see acoustic modelling report; Appendix 2)	DHI

3.3.4 Environmental baseline survey equipment

Seabed morphology, seabed bathymetry and presence of biota on the seabed are determined by acoustic means through high resolution Side Scan Sonar (min 500 kHz, SSS) and Multi Beam Echosounding (200 or 400 kHz, MBES). The SSS and MBES will be Remote Operated Vehicle (ROV) or Autonomous Underwater Vehicle (AUV) mounted. Figure 3-3 illustrates a typical vessel for EBS.

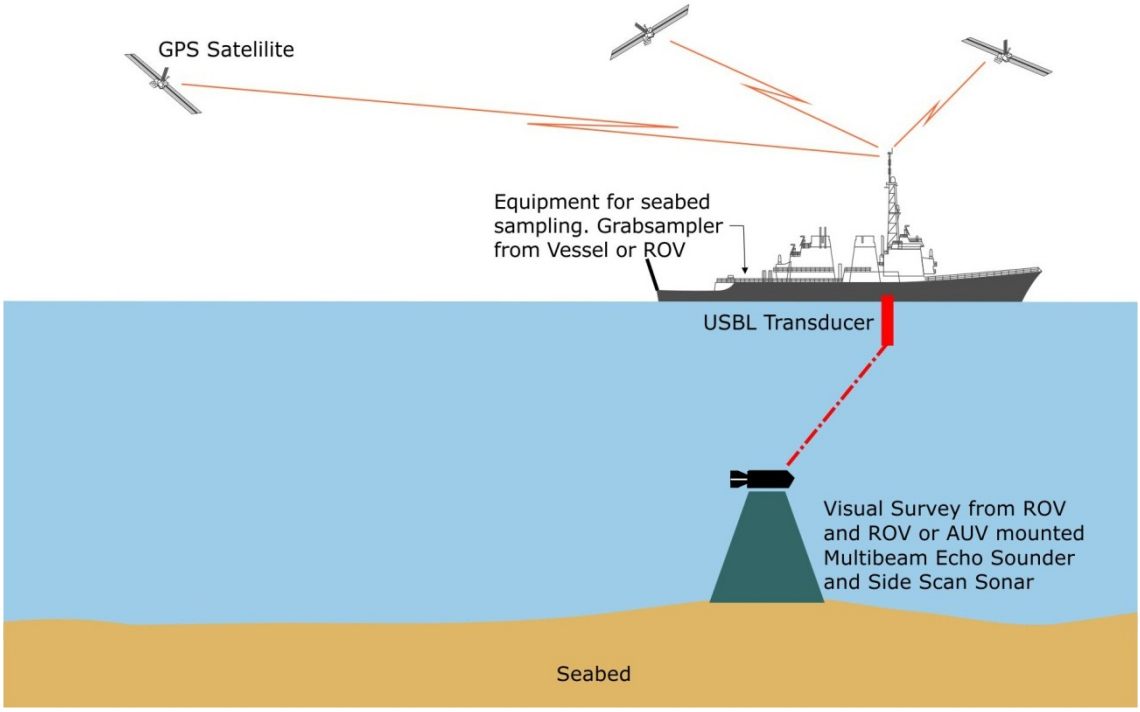

Figure 3-3 Schematic illustration of a typical environmental baseline survey.

Visual inspection will be carried out by means of an HD camera mounted on a ROV. Visual inspection and analysis is required for geophysical and biological seabed features. The visual surveys are executed cautiously to ensure that it does not cause damage to biota, especially if the target includes corals and/or sponges. Visual inspections will be carried out on seabed features with areas >25 m^2. A maximum of 3 inspections per survey site is expected..

Benthic and sediment sampling is proposed in eight stations for each of the survey sites to enable characterisation of benthic invertebrate assemblages and physical/chemical characterization as per OSPAR guidelines. Additional characterisation of epifauna will also be achieved through sampling at the seabed.

Numbers of samples and sampling strata associated with the physical and chemical analysis sediment samples will vary by parameter. The planned methods of collecting sediment samples as well as number of samples and sample specifications are indicated in Table 3-6 for each survey site. The physical footprint will depend on the actual sampling device and the number of samples. Assuming an impact area of 0.1 to 0.25 m^2 per sample and a number of rejected samples, a total area of 70 m^2 per survey site is roughly estimated.

Table 3-6 Planned EBS sampling and methods for each of the three survey sites

Sampling	Method	Station	Samples	Specifications
Seabed bathymetry	Side scan sonar and multi beam echosounder	Minimum area of 3 km x 3 km per survey site	-	-
Seabed features	Remotely operated vehicle w/ HD camera	Dependent on acoustic survey	-	-
Surficial sediment (Benthic invertebrate)	Box corer and/or grab sampler	Minimum of 8 stations per survey site	Minimum of 70 per survey site	Volume of each sample is 0.02 m^3 (0.32x0.32x0.2 m^3)
Surficial sediment (Chemistry)	Box corer and/or grab sampler	Minimum of 8 stations per survey site	Minimum of 116 per survey site	Weight of samples is between 50 and 300 g per sample Maximum depth of sampling is 6 cm
Epifauna	Small bottom trawl or dredge	Dependant on acoustic and ROV survey	One tow per sampling station	Contents of trawl or dredge

3.3.5 Metocean and PAM buoys

The monitoring equipment for the metocean and PAM buoys requires a means of securing them to the seabed. For ease of handling and deployment, steel weights are used as ballast. This is a relatively common method of securing such moorings and provides the necessary ballast which is easy to deploy and has a small seabed footprint. During deployment of the buoys it is possible that the steel weight will settle into the seabed. The planned method for recovery is to leave the steel weights on the seabed following recovery of the equipment. This will leave a physical footprint of less than 1 m^2 per buoy and the weights would degrade slowly over time.

An example of an metocean buoy setup is illustrated in Figure 3-4.

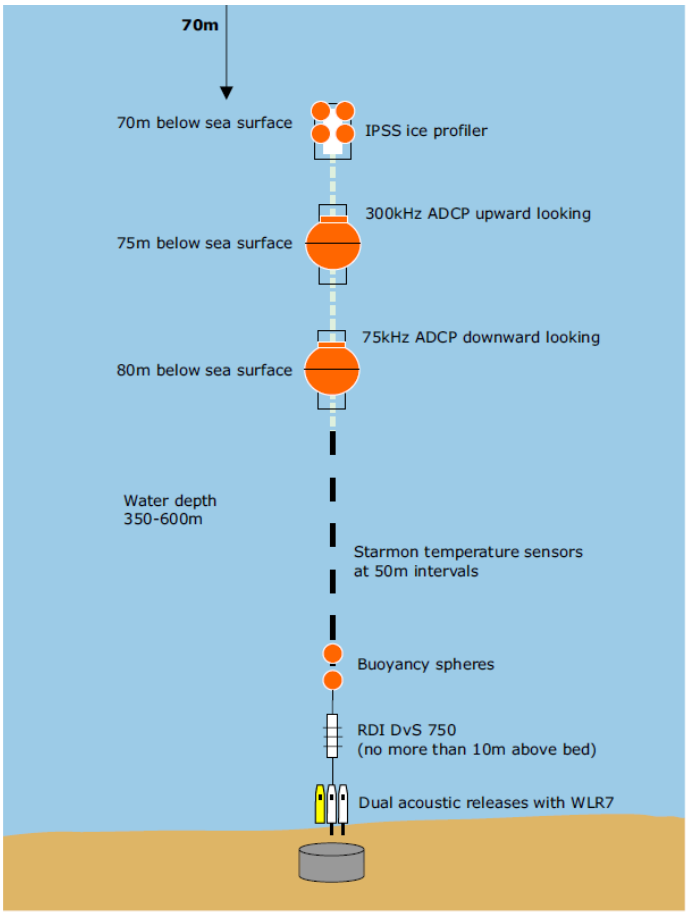

Figure 3-4 Principle of oceanographic mooring setup

3.4 Logistics

Upernavik is the proposed primary port for medical emergency response, with Aasiaat proposed as an alternative base.

Crew changes as needed are planned executed through the nearest suitable port or by crewboat from Upernavik.

Bunkering and resupply will only take place in accordance with the Manual of Permitted Operations (MOPO) developed specifically for this operation once the contractor has been selected.

Approximately 35 and 50 personal are expected to be stationed onboard the survey vessels for the 2D HR seismic survey and the EBS respectively, assuming two vessels.

A comprehensive ice management plan will be developed as part of the project preparations. The plan will outline how icebergs and growlers will be dealt with to ensure a safe operation of the vessel during operations and transit. This will include systems for iceberg/growler detection, tracking and avoidance procedures.

Icebreaker assistance is not expected, as the survey will only take place during conditions without first year ice.

3.5 Waste, emissions and discharges

3.5.1 Emissions to air

The main source of emissions to the atmosphere will be from the vessel's engines. The vessels will use marine gasoil with sulphur content less than 1.5 % (weight).

It is roughly estimated that the total fuel consumption from both the seismic vessel and the EBS vessel is expected to be approximately 2,500 tonnes in total for both surveys (EBS and seismic).

Standard industry emission factors /8/ are used to estimate emissions to air based on the fuel usage of 2,500 tonnes. The total emissions are presented in Table 3-7.

Table 3-7 Estimated emissions to air from vessels during 2013 survey

Component	Estimated total emissions (tonnes)
CO_2	7925
NO_x	175
Nm VOC	13
SO_x	7
N_2O	1
CO	18

3.5.2 Vessel liquid discharges

The main liquid effluents generated by the survey vessels will comprise:

- Greywater (water from culinary activities, shower and laundry facilities, deck drains and other non-oily waste water drains (excluding sewage))
- Treated blackwater (sewage)
- Drainage water
- Service water / vessel engine cooling water.

All discharges will comply with requirements set out in the International Convention for the Prevention of Pollution from Ships, 1973, as modified by the Protocol of 1978 (MARPOL 73/78) and its annexes.

The total volumes of planned discharges (from both EBS and seismic survey, assuming to vessels) are estimated at 4,500 litres of treated blackwater and 13,000 litres greywater. These estimates assume that black water and grey water are produced at a rate of up to 50 litres and 150 litres per person per day respectively /5/, for the expected number of persons on board i.e. 35 persons (EBS) and 50 persons (seismic survey). The total volume of discharged service water is expected to be small and spread over a large offshore area.

3.5.3 Vessel solid wastes

All solid wastes will be sorted by type, compacted where practicable and stored on board before disposal to an appropriate certified onshore reception facility. It is proposed that the survey vessels will bag solid waste materials and store them on board for disposal on return to the vessel's home ports. Should waste disposal be required in Greenland, an appropriate port will be used to provide waste handling / disposal facilities. Food waste will be macerated and disposed at sea. All wastes during the survey will be managed in accordance with MARPOL requirements, relevant national legislation and best practice principles.

3.5.4 Lights

During the open water season there is constant light in the Baffin Bay area until dark nights start in early September.

At 74°N, the midnight sun period, with the sun continuously above the horizon lasts from April to August. Up to the 12 h day/12 h night at autumn equinox (21st September) the number of daylight hours decrease gradually. By the end of the survey window (October), the day-length will have decreased to approx. 4 hours in the survey area, and by November 7, the polar night engulfs the survey area. The need for on-deck illumination thus increases during the survey.

All survey vessels will carry appropriate navigation lights for periods of poor visibility and night-time, including ice searchlights.

3.5.5 Noise

The vessels and the 2D HR seismic survey and other geophysical equipment generate underwater noise.

The largest sound pressure level will be generated by the survey airgun and the frequency content of the emitted pulse will be a function of the total airgun volume (see section 5.2.1). The signal is focused in a downward direction to limit spreading of sound.

High resolution seismic site survey uses a much smaller airgun than other seismic surveys, which typically use airgun arrays with a capacity far greater than 1,000 in^3. The airgun size expected for this survey is 160 in^3. Typical noise levels produced are presented in section 5.2.1.

3.6 Demobilisation

Demobilisation is pending further planning when contractor is selected. The vessels may demobilise in Greenland from the survey areas on completion of the site survey.

4. CONSIDERED ALTERNATIVES

4.1.1 Timing

The survey schedule is predominantly determined by ice conditions in the area, as well as availability of a suitable vessel tailored to operating in these conditions. Ice cover for much of the year prevents vessel movements in the area over large periods of time. The survey period between July 15th and October 15th 2013 has been identified as the open water season when the site survey can be carried out. No other alternatives could be considered.

4.1.2 Survey equipment

The proposed survey equipment uses sound of different frequencies and amplitudes to map the seabed and shallow sediments. The range of equipment provides varying degrees of coverage, detail and penetration into the seabed. The equipment has been selected to provide the coverage and detail required to address any potential seabed or shallow hazards.

The high resolution seismic spread will use an airgun to generate the seismic signal. Alternative sound sources include explosives and water guns, however, the air gun is preferred as it is the safest, most reliable and provides a consistent signal required for acquiring data. The airgun source proposed for this site survey is far smaller than the airgun source used for typical seismic surveys, which will often be in the order of twenty times larger. The smallest size of airgun will be used which is capable of delivering the signal strength required to map the sub-surface and identify potential hazards as per the survey scope of work.

The survey will utilise a towed streamer to record the returning sound signal generated by the airgun or airguns. An alternative to the use of a towed streamer is the use of Ocean Bottom Sensors. With this technique, cables are placed on the seabed with hydrophones and geophones to detect the reflected waves from the sound source. This technique is not suitable for use during a high resolution site survey which is of short duration. Instead, Ocean Bottom Sensors are primarily used for longer term projects where the sensors can remain in place over long periods. A towed streamer is therefore considered to be a relatively simple and safe method of seismic acquisition.

5. IMPACT ASSESSMENT (PLANNED EVENTS)

The environmental impact assessment (EIA) addresses a number of physical, chemical, biological and some socioeconomic parameters. For each parameter, a description of existing conditions is presented. The existing conditions are presented with reference to the recent strategic environmental impact assessment (SEIA) of Baffin Bay /9/ where appropriate. Since the license blocks are located more than 85 km from the coast, coastal resources and topics have largely been considered outside the area of influence for the site survey. As recommended in the seismic EIA guidelines /3/, focus is on the biological components of the environment that are most likely to be influenced by the site survey.

Based on the description of the existing conditions, an assessment of environmental impacts is performed. A set of impact factors related to the survey are identified, and potential impacts are assessed along the classical assessment lines: time, space and magnitude, in accordance with the methodology presented in section 5.1.

5.1 Method for impact assessment

The impact assessment is based on the survey plans as they appeared by late January 2013, and the description of the existing environment. Both planned and unplanned (accidental) impacts (resulting from planned and unplanned events, respectively) are assessed. This section describes the methodology used to assess the environmental impacts associated with the 2013 site survey.

Environmental impacts include both direct and any indirect, secondary, short-, medium- and long-term, permanent and temporary, positive and negative impacts caused by the project.

The methodology used for assessment of impacts includes criteria for categorizing environmental impacts. The impact assessment includes:

- Identification of potential project impacts
- Nature, type and reversibility of impact
- Intensity, scale and duration of impacts
- Sensitivity of resource/receptor
- Overall severity of impacts

The impact assessment methodology serves to provide means of characterising identified impacts and their overall severity. Following the assessment of overall severity, a further assessment of residual impacts are performed. Residual impact assessesthe impact upon the receiving environment after implementation of mitigation measures.

5.1.1 Identification of potential project impacts

The first step of identifying potential impacts consists of an identification of which sources or activities in the project may result in potential impacts and which receptors may be affected. Typical impacts are associated with:

- Noise
- Physical disturbance
- Waste
- Discharges to sea
- Emissions to air
- Light
- Unplanned events (assessed in section 6)

5.1.2 Nature, type and reversibility of impact

Impacts are initially described and classified according to their nature (either negative or positive), their type and their degree of reversibility. Type refers to whether an impact is direct, indirect, secondary or cumulative. The degree of reversibility refers to the capacity of the impacted environmental component/resource to return to its pre-impact state.

Nature, type and reversibility are elaborated upon in Table 5-1.

Table 5-1 Classification of impacts: Nature, type and reversibility of impacts

Nature of impact	
Negative	An impact that is considered to represent an adverse change from the baseline (current condition) or to introduce a new, undesirable factor.
Positive	An impact that is considered to represent an improvement to the baseline or to introduce a new, desirable factor.
Type of impact	
Direct	Impacts that result from a direct interaction between a planned project activity and the receiving environment.
Indirect	Impacts that result from other activities that are assessed to happen as a consequence of the project.
Secondary	Impacts that arise following direct or indirect impacts as a result of subsequent interactions within the environment.
Cumulative	Combined impacts of other survey activities and other human activities in the area (e.g. fishery)
Transboundary	Impacts across borders, i.e. impacts to the Canadian part of Baffin Bay.
Degree of reversibility	
Reversible	Impacts on resources / receptors that cease to be evident, either immediately or following an acceptable period of time, after termination of a project activity.
Irreversible	Impacts on resources / receptors that are evident following termination of a project activity and that remain for an extended period of time. Impacts that cannot be reversed by implementation of mitigation measures.

5.1.3 Intensity, scale and duration of impacts.

Predicted impacts are defined and assessed in terms of a number of variables, primarily intensity, scale and duration of an impact. Ascribing values to the variables are, for the most part, objective. However, awarding a value to certain variables may be subjective in that the extent, and even direction, of change often is difficult to define.

An explanation of the classifications and values applied in the EIA is presented in Table 5-2.

Table 5-2 Classification of impacts in terms of Intensity, scale and duration.

Intensity of impacts	
No impact:	No impacts on structure or function of the resource/receptor within the affected area.
Minor impact:	Minor impacts on structure or function of the resource/receptor within the affected area, but basic structure and /function remain unaffected.
Medium impact:	There will be partial impacts on structure or function inside the affected area. Structure/function of the resource/receptor will be partially lost.
Large impact:	The structures and functions of the resource/receptor are altered completely. Structure/function loss is apparent inside the affected area.
Geographical extent of impacts	
Local impacts:	There will be changes in the immediate vicinity of the survey area. Impacts are restricted to the survey sites (3x3 km).
Regional impacts:	There will be impacts outside the immediate vicinity of the survey sites (local impacts), and up to around 10 km outside the survey sites.
National impacts:	Impacts will be restricted to Greenland.
Transboundary impacts:	Impacts will be experienced outside of Greenland.

Duration of impacts	
Immediate:	Impacts during and immediately after the construction; however the impacts stop immediately when the activity is stopped.
Short-term:	Impacts throughout the period of site survey and up to one year after.
Medium-term:	Impacts that continue over an extended period, between one and ten years after the site survey.
Long-term:	Impacts that continue over an extended period, more than ten years after the site survey.

5.1.4 Sensitivity of resource/receptor

The overall significance of the impacts is evaluated on basis of the evaluation of the single impact variables, as described above, and on the sensitivity of the resource/receptors affected.
It is imperative to place some form of value (low, medium and high) on a resource/receptor that could potentially be affected by project activities. Such a value may be regarded as subjective to some extent.

However, expert judgement and stakeholder consultation ensure a reasonable degree of consensus on the intrinsic value of a resource/receptor. The allocation of a value to a resource/receptor allows for the assessment of a resource's/receptor's sensitivity to change (impact). Various criteria are used to determine value/sensitivity, including, amongst others, resistance to change, adaptability, rarity, diversity, value to other resources/receptors, naturalness, fragility and whether a resource/receptor is actually present during a project activity. These determining criteria are elaborated upon in Table 5-3.

Table 5-3 Criteria used to evaluate sensitivity of resource/receptor.

Sensitivity	
Low:	A resource / receptor that is not important to the functions/services of the wider ecosystem or that is important but resistant to change (in the context of project activities) and will naturally and rapidly revert to pre-impact status once activities cease.
Medium:	A resource / receptor that is important to the functions/services of the wider ecosystem. It may not be resistant to change, but it can be actively restored to pre-impact status or will revert naturally over time.
High:	A resource / receptor that is critical to ecosystem functions/services, not resistant to change and cannot be restored to pre-impact status.

5.1.5 Overall severity of impacts

The severity of the impact is then defined by comparing the intensity of the impact of the project and the sensitivity of the environmental receptors. It is qualified according to a scale which ranges from "none" to "significant", defined as presented in Table 5-4.

Table 5-4 Criteria for evaluation of the severity of impacts

Severity of impacts	
No impact:	There will be no impact on the environment.
Minor impact:	Minor adverse changes that might be noticeable, but fall within the range of normal variation. Impacts are short-term and natural recovery takes place in the short term.
Moderate impact:	Moderate adverse changes in an ecosystem. Changes may exceed the range of natural variation. Potential for natural recovery in the medium-term is good. However, it is recognised that a low level of impact may remain.
Significant impact:	The structure or function in the area will be changed, and the impact will also have impact outside the license blocks.

In the environmental impact assessment, every resource/receptor assessed will be accompanied by a table summarizing the assessment of the different variables of intensity, scale and duration,

and sensitivity of resource/receptor as well as the overall severity to give the reader a brief overview of the impacts, see Table 5-5.

Table 5-5 Criteria used in the environmental impact assessment for the Shell 2013 site survey.

Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact[1]
None	Local	Immediate	No impact
Minor	Regional	Short-term	Minor impact
Medium	National	Medium-term	Moderate impact
Large	Transboundary	Long-term	Significant impact

[1]: Evaluation of overall significance of impact includes an evaluation of the variables shown and an evaluation of the sensitivity of the resource/receptor that is assessed.

Positive impacts are shown with a "+" in the comprehensive tables for the potential impacts.

5.1.6 Level of confidence

An assessment of scientific certainty (low, medium, and high levels of confidence) will be provided based on our confidence in the scientific information available when we have judged an impact as having a particular negative impact. Criteria are elaborated upon in Table 5-6.

Table 5-6 Criteria used to evaluate confidence of resource / receptor.

Confidence	
Low:	Based on incomplete understanding of cause-effect relationships and/or incomplete data specific to the License blocks.
Medium:	Based on good understanding of cause-effect relationships using data from elsewhere or incompletely understood cause-effect relationships using data specific to the License blocks.
High:	Based on good understanding of cause-effect relationships and data specific to the License blocks.

The category "high" is also applied where the assessment is based on a highly confident knowledge that the impact factor will not overlap with the resource, despite lack of local data.

5.1.7 Residual impact

Based on the assessment of the overall severity of impact, as described above, a residual impact is assessed. The residual impact is the impact upon the receiving environment after implementation of mitigation measures.

5.2 Summary of potential project impacts

The potential project impacts resulting from the planned 2013 site survey are summarized in Table 5-7, based on the project description (see section 3).

Table 5-7 Summary of potential project impacts. For details, please refer to section 3.

Potential project impact	Summary based on section 3
Physical disturbance from vessels and equipment	During the site survey up to two vessels are expected in the area (EBS and seismic vessel). The site survey is planned to be undertaken in the period between the 15th July and 15th October 2013. No 2D HR seismic shots will be fired before 1st of August 2013.
Noise	The 2D HR seismic survey equipment and the vessel propeller systems generate an amount of underwater noise. The largest sound pressure level will be generated by the survey airgun. As underwater noise is considered a primary impact, special focus will be given to this. Acoustic modelling is presented below.
Waste	All solid wastes will be sorted by type, compacted where practicable and stored on board before disposal to an appropriate certified reception facility. No waste will be abandoned offshore.
Planned discharges	All discharges will comply with requirements set out in MARPOL. The total volume of discharges (both EBS and seismic survey) is estimated at 4,500 l blackwater and 13,000 l greywater. The volume is discharged throughout the survey period, over a large offshore area.
Emissions	Emissions have been estimated based on fuel consumption in relation to the 2013 site survey. Total emissions (both EBS and seismic survey) are estimated at 7,925 ton CO_2, 175 ton NO_x, 13 ton nmVOC, 7 ton SO_x, 1 ton N_2O and 18 ton CO_2.
Light	All survey vessels will carry appropriate navigation lights for night-time and periods of poor visibility, including ice searchlights.
Unplanned events	Unplanned events are addressed in section 6.

5.2.1 Acoustic noise modelling

The 2D HR seismic surveys introduce sound pressure levels that have the potential to impact marine life (marine mammals and fish) at the sites and in adjacent areas. Acoustic modelling has been performed for the site survey, in accordance with the BMP guidelines and the model includes an estimate of the noise levels included in the model and the numerical modelling of the propagation loss from source out to a distance where impacts are not considered biologically important for the receivers.

An introduction to sound is presented in Appendix 1, presenting sound terminology. The acoustic modelling is included in Appendix 2.

An overview of the areas that will be explored using 2D seismic survey, as well as the Environmental Baseline Survey (multi-beam echosounder and side-scan sonar) is shown in Figure 5-1. The site survey will take place at up to ten locations within the proposed survey area. The noise modelling of the 2D seismic surveys is based on modelling at three sites (3x3 km) around proposed sites occurring at depths of 500 – 800 m. Noise generated by the additional survey methods (multibeam echosounder, side scan sonar) is also assessed. The modelling is presented in Appendix 2, and the results are summarised in this section.

Multi-beam echosounders are used to provide a detailed estimate of water depth. The equipment model Kongsberg EM 1002 multibeam echosounder produces pulsed signals with a duration of either 0.2, 0.7 or 2 msec. The main energy is centred around 95 kHz, and source sound pressure levels are reported to be 225 dB re 1µPa /14/.The beam pattern is broad in the plane defining the width of the echosounder's transducer and narrow in the plane defining its height.

Side-scan sonars use extremely high-frequency (100-500 kHz) pulses to map the upper layers of the seabed. The pulses are of very short duration (300-600 µsec), and source sound pressure levels are between 220-226 dB re 1µPa /14/.

2D High resolution seismic survey to investigate the proposed locations for drilling. The surveys are similar to conventional 2D seismic surveys, except that the source used is comprised of a smaller volume of compressed air such as in this case with the overall 160 cubic inches involving only four airguns. Looking at the source strength, Genesis /14/ and Wyatt /16/ provide a comprehensive review of a variety of airguns and airgun arrays. According to their analysis, the emitted sound field is a function mainly of the size and the number of airguns and the overall emitted psi values.

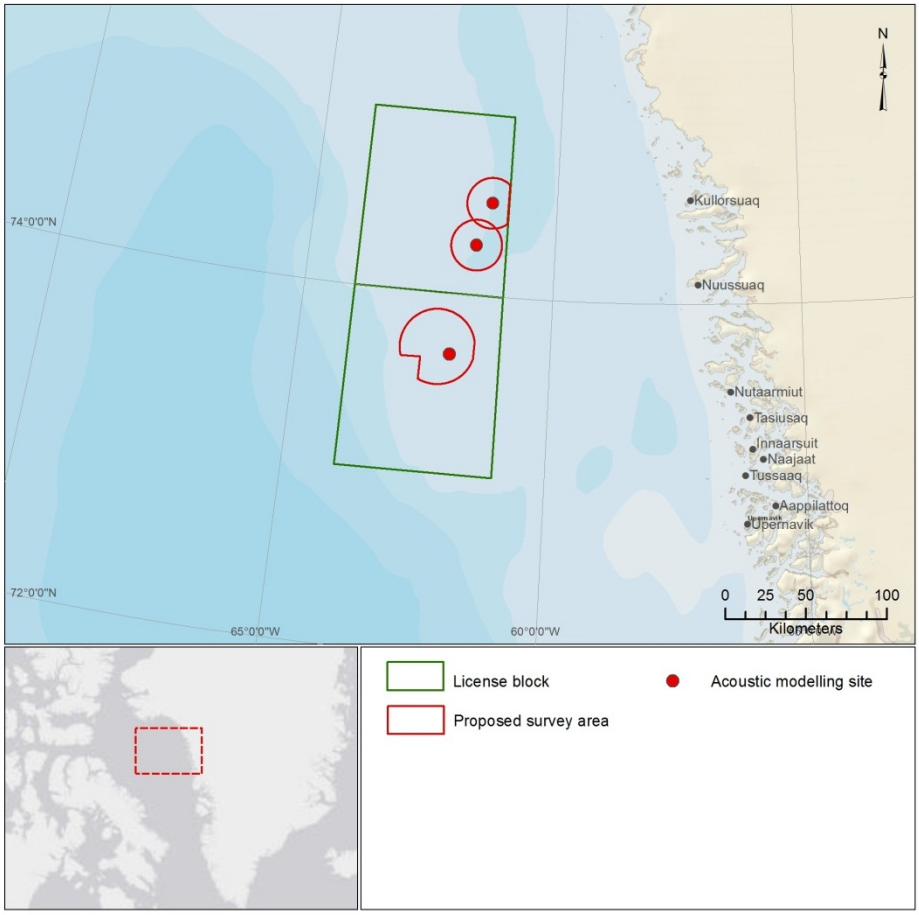

Figure 5-1 Overview of the survey areas and the three locations for which the modelling of the 2D seismic surveys was undertaken.

Based on information from the literature (for example /14/) we derived a zero-to-peak value of 230 dB re 1 µPa for the type of airgun array assessed to be used in the site survey. The difference between the zero-to-peak values and the peak values was set at 6 dB resulting in a peak-to-peak source sound pressure level of 236 dB re 1 µPa for the array /14/.

For the frequency spectrum we used a modelled far-field signature and the corresponding frequency spectrum for frequencies up to 1 kHz of a representative array (see /65/) and scaled it to meet the source strength identified for this study. We decided to include frequencies of up to 4 kHz (see Madsen /15/). For frequencies above 1 kHz, the source spectrum was extrapolated assuming an 18 dB / octave slope (see, for example Wyatt /16/). The resulting spectrum is shown in Figure 5-2.

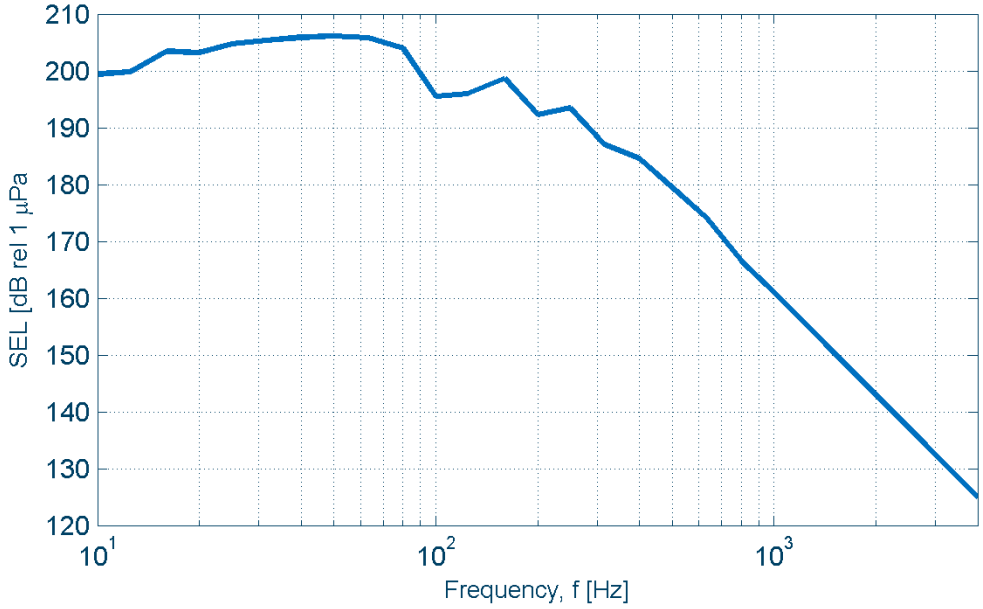

Figure 5-2 Frequency spectrum of seismic survey array far field signature.

Based on the derived spectrum, the resulting broadband SEL level was 214 dB re µPa^2·s. Genesis /14/ lists zero-to-peak and SEL values for a variety of airguns and airgun arrays, and based on their review it can be seen that on average the SEL values are about 20 dB below the zero-to-peak values. RMS values can then be derived from SEL values (see review by OSPAR /17/).RMS values could be derived by adding 13 dB to the corresponding SEL values.

5.2.2 Modelling results – summary of Appendix 2

2D seismic surveys are to take place at up to ten locations in Baffin Bay. The surveys will be restricted to areas (3x3 km) around proposed drilling sites and will occur at depths of 500 – 800 m. We present the results of an acoustic propagation modelling study of the expected noise exposure from the planned 2D seismic surveys to be included in the supplied EIA. The model is based on actual bathymetry information covering the entire area and basic knowledge of sediment properties. We also used detailed data on the vertical sound speed profiles during the time of the proposed survey (July – October). Horizontally, our model intends to cover all areas exposed to levels likely to affect marine mammals. Different from previous investigations, we also include frequencies above 2 kHz in the modelling to better match the acoustic sensitivity of some of the marine life in the area.

Based on information about the airgun array that will be used and literature data the acoustic modelling used a zero to peak source sound pressure level of 230 dB re 1 µPa as the input variable in this study. The resulting peak to peak source sound pressure level was defined as 236 dB re 1 µPa. For the frequency spectrum we used a modelled far-field signature and the corresponding frequency spectrum of a representative array and scaled it to meet the source strength identified for this study. Based on the derived spectrum, the resulting broadband SEL level was 214 dB re µPa^2·s. RMS values were directly derived from SEL values and resulted in a source sound pressure level of 227 dB re 1 µPa. The calculation of the sound levels at different distances from the sources was undertaken for frequencies up to 4 kHz using a 2D numerical model of the underwater acoustic propagation. The well-established AcTUP package was used, applying the RAMGEO code which is a full Parabolic Equation model.

An example of the noise propagation maps produced in the acoustic modelling is shown in Figure 5-3.

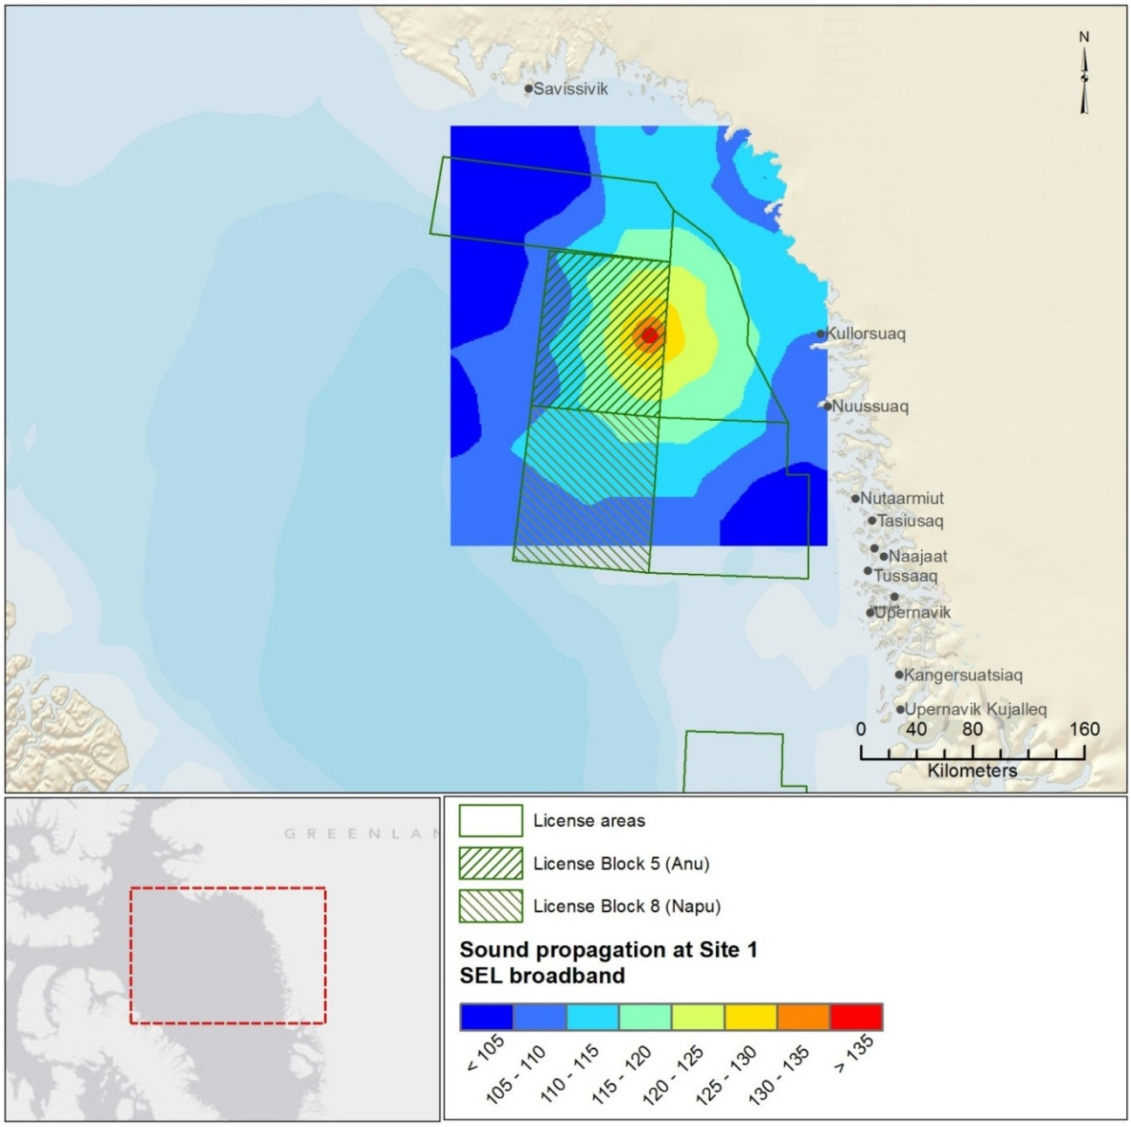

Figure 5-3 Example of noise propagation map at one of three sites where acoustic modelling has been undertaken [units are in dB re 1 µPa^2·s].

The results of the modelling show a sharp decrease of sound levels in the first km from the source and a smoother decline in sound pressure levels at a longer range. Higher frequencies than 1 kHz where attenuated more rapidly than those below 1 kHz although not as drastically as expected. Furthermore, the difference in propagation loss across sites was very small indicating that results obtained here can be transferred somewhat to other sites if the development is relocated.

Looking at the cumulative sound fields (sound over a 24 h period including the survey), it is clear that impact ranges can be larger than for single shots. Yet, the assumption that the acoustic energy just sums up at the receiver in the way suggested by the calculations, neglects that hearing might recover between pulses. Thus, the overall impact from the survey over the course of a one-day cycle might be smaller than indicated in the cumulative maps.

The survey area will comprise 3 x 3 km with transects at each 100 m. It will take app 12 h to travel this distance with the assumed survey speed of 4 kn. The total survey area will be this 90 km^2.

5.3 Climate and ice conditions

5.3.1 Existing conditions

As described in the SEIA /9/, the weather conditions in the Baffin Bay area are influenced by the North American continent and the North Atlantic Ocean, but also the Greenland Inland Ice and

the steep coasts of Greenland have a significant impact on the local weather. Atlantic depressions frequently cause strong winds off West Greenland. Also more local phenomena such as fog are common features near the shore.

Midnight sun, when the sun is continuously above the horizon, lasts from the 30th of April to the 12th of August at 74 °N. Up to the 12 h day/12 h night at autumn equinox (21st September) the number of daylight hours decrease gradually. By the end of the survey (mid October), the day-length will have decreased to approx. 4 hours in the survey area, and by November 7, the polar night engulfs the survey area.

The license blocks are situated within the Arctic climate zone, with average air temperature below 10° C year round. Summer temperatures over the ocean are usually close to surface water temperatures, which typically range from -1.8 to 5 °C.

In winter the waters of Baffin Bay are normally covered with sea ice from December to June. Two types of sea ice occur: fast ice, which is stable and anchored to the coast, and drift ice, which is very dynamic and consists of floes of varying size and density. The drift ice is often referred to as 'The West Ice' because it is formed to the west of Greenland /9/. The maximum extend of the west ice is usually seen in late March. In addition to sea ice, icebergs originating from calving glaciers occur in the entire region, and may be encountered during the site survey /10/.

5.3.2 Impact assessment

The **emissions** associated with the site survey (from up to two vessels) have been assessed in section 3.5. The estimated emissions from the site survey are considered comparable to those from other vessels in the area. It is assessed that no measurable impacts on climate and ice conditions will occur.

Table 5-8 Environmental impacts to climate and ice conditions in connection with the 2013 site survey.

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Emission of greenhouse gasses	Minor	Local	Long-term	No impact	High

5.4 Oceanography

5.4.1 Existing conditions

The oceanography in the license blocks and in Baffin Bay was reviewed in detail in an EIA from 2012 /6/, and is briefly summarized in the following.

The currents in Baffin Bay are dominated by a strong southward flow of cold water and ice from the Arctic Ocean. The relatively warm West Greenland Current crosses Baffin Bay from east to west.

Because of the moderate wind conditions in Baffin Bay, wave heights are characteristically small, usually below 1.7 m for the four-month period August–November, 1985–1996 /19/. Larger waves can occur, but these are usually of short duration. Waves have minimum levels in the early summer months when considerable amounts of sea ice are present as well as the lower summer winds, whereas larger waves occur in the fall with more open water and higher winds.

The water temperature at the surface is below −1 °C in winter. In summer, the surface temperature varies from 4–5 °C to 0 °C. At deeper waters, the temperature is low throughout the year. The salinity exceeds 34 ‰ in winter, partly due to sea ice formation, while summer salinity is typically 30-32 ‰.

5.4.2 Impact Assessment

In general, the oceanography in Baffin Bay is a product of large-scale and global processes. Presence of vessels performing seismic and environmental surveys within a period of a few months will not impact the oceanography.

Table 5-9 Environmental impacts to oceanography in connection with the 2013 site survey.

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
-				No impact	High

5.5 Bathymetry

5.5.1 Existing Conditions

The coastal zone of the region is dominated by rocky shorelines with many archipelagos. Small bays with sand or gravel are found in sheltered areas. The Northern part (from Kullorsuaq and to Savissivik in the North) the coastal line is dominated by glaciers with Nunataks /10/.

The bathymetry of Baffin Bay with shallow sills both to the north and south creates a relatively isolated body of cold, deep, polar water. The shelf in eastern Baffin Bay is shallow (less than 200 m) and is generally a narrow strip (usually less than 80 km wide) along the coast and some banks. Outside the shelf depths reach more than 2,000 m in central parts of the bay /10/.

In the two license blocks, the depths vary from c. 150 m in the northwestern area and 2000 m in the southwest corner of the license blocks. The main part of the license blocks are at depths of 400-800 metres.

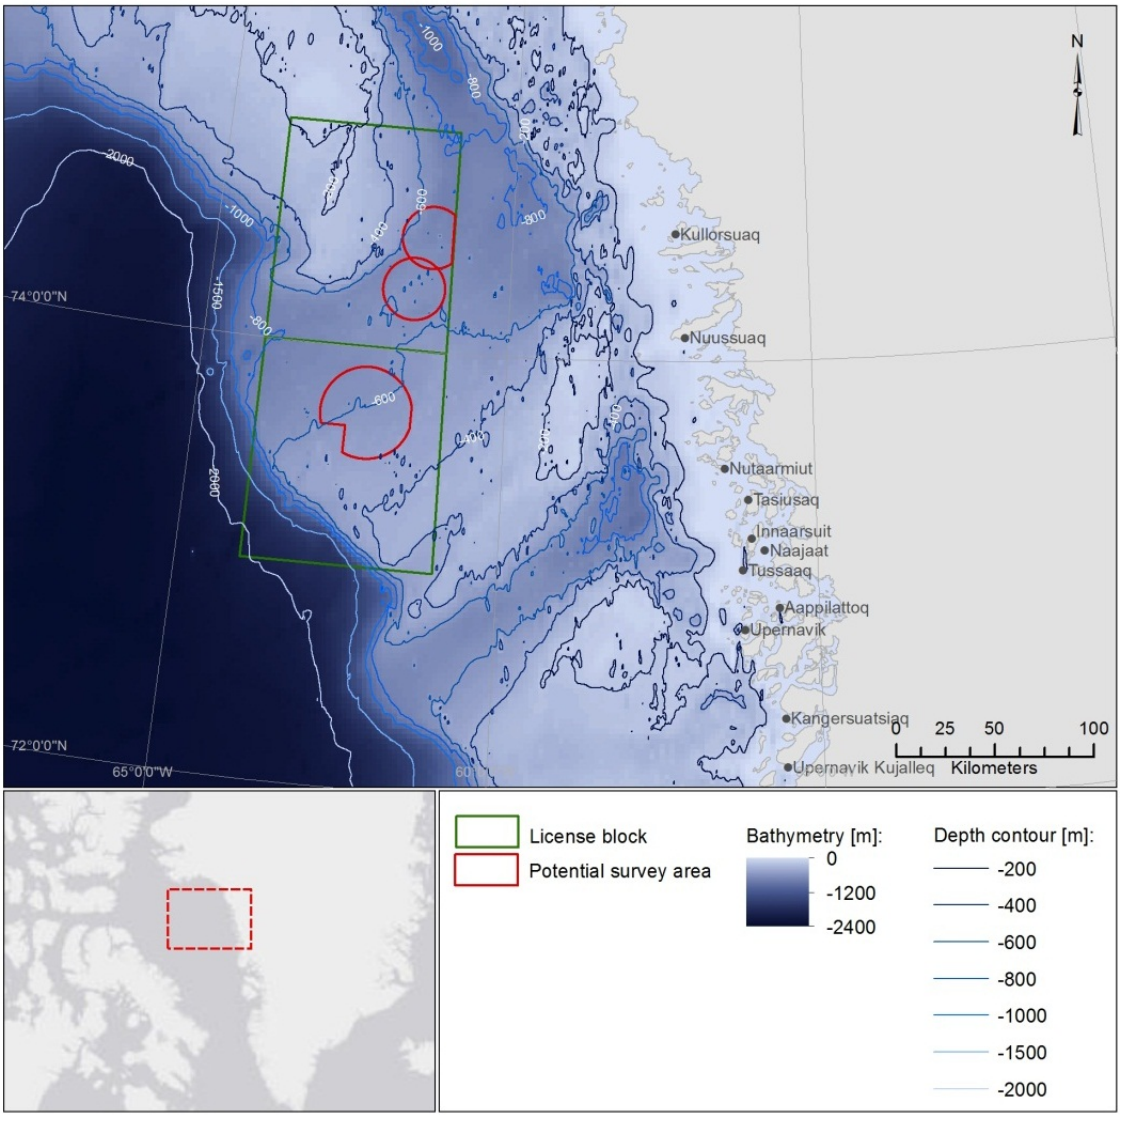

Figure 5-4 Bathymetry in Baffin Bay and the license blocks

5.5.2 Impact Assessment

As part of site survey, there will be some removal and relocation **of seabed material** in connection with grab/boxcorer sampling, trawl, ROV usage and deployment of moorings for oceanographic measuring equipment. This disturbance will be in the surficial sediment layers, and sampling will leave a shallow depression in the seabed. In areas of accumulation, sediments from neighbouring areas and fall-out from the water column will gradually re-fill such sampling marks, though this may take some time. The actual time will depend of the depths of the depressions and is assessed to be medium-term (1-10 years).

Based on the very local disturbance, and the medium-term duration, the disturbance is assessed to have no impact on the bathymetry of the area.

Table 5-10 Environmental impacts to bathymetry in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Seabed disturbance	None	Local	Medium-term	No impact	High

5.6 Water and sediment quality

5.6.1 Existing conditions

A benthic survey /6/ was done with a drop camera along 11 transects in the northern license block, and further north at depths of 600-750 m. These are the same depths as the planned 2013 site survey. Sediments consisted mainly of fine sand, and a few spread locations of gravel or gravel/sand mixture. Cobble, rubble, boulders, and shells accounted for minor proportions of the observed substrate at most survey sites.

In general, information on contaminants in water and marine sediments are only available near local discharge point, e.g. cities, settlements, former mine sites and Thule Airbase. Thus, no local sediment data from the survey sites exist, but in 2008, polycyclic aromatic hydrocarbons (PAH) were analysed in the surface sediment layer (0-1 cm depth) of Baffin Bay /20/. PAH levels were generally low and could be regarded as background levels.

The occurrence of contaminants in the marine environment and their potential impacts on biota has been studied in Greenland. Based on studies of contaminants in organisms, as summarized in the SEIA /9/, the overall conclusion was that lead levels in marine organisms from Greenland were low, whereas cadmium, mercury and selenium levels were high. No clear conclusions could be drawn in relation to geographical differences.

5.6.2 Impact assessment

Disturbance of seabed in relation to site survey sampling, ROV usage and deployment buoy anchors is expected to cause suspension of fine grained sediments, which subsequently resettle on the seabed. Such short-term, local disturbance is assessed to be of no impact to water and sediment quality.

Discharges of grey water and treated black water can lead to increased organic load of the sediments. This can in extreme cases stimulate growth in and changes of benthic faunal assemblages. . However, the release of fine particular material in a stream of freshwater will sink very slowly towards the seabed, and at 600 – 700 m depth, it will be spread over a large area and is not expected to cause any measurable impact on water or sediment.

Table 5-11 Environmental impacts to water and sediment quality in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Suspended sediments	Minor	Local	Short-term	No impact	High
Discharges	Minor	Local	Short-term	No impact	High

5.7 Plankton

5.7.1 Existing conditions

As described in the SEIA /9/, total primary production in the arctic is from three sources: phytoplankton, ice algae on the underside of fast or drift ice, and benthic algae. In most of Baffin Bay, there is a brief and intense phytoplankton bloom immediately after ice break-up in spring, with high transient phytoplankton biomass and relatively low total primary production integrated over depth and season. Exceptions are polynyas (which is not previously registered in the license blocks), areas of open water surrounded by ice, some of which are recurring and remaining open throughout the winter.

Zooplankton provides the main pathway to transfer energy from phytoplankton to consumers at higher trophic levels, e.g., fish, and thus has a critical role in marine food webs. High latitude zooplankton production follows the extremely strong seasonal pulse of phytoplankton. Numerous taxa are included, but copepods, particularly calanoid copepods, are dominant.

Studies carried out near Melville Bay showed that the most dominant copepod species are *Calanus hyperboreus*, *C. glacialis*, and *C. finmarchicus*. Their vertical distribution was linked to food availability, salinity, and temperature. The genus *Calanus* was most abundant in water with temperatures below <0 °C, whereas other species were most abundant at temperatures >0 °C /9/.

Although copepods are typically predominant in Arctic marine systems, there is a broad assemblage of other planktonic groups and their role has yet not fully been understood /9/.

The knowledge on plankton is not yet sufficient to designate any important or critical areas within Baffin Bay, except for the north water polynya which is situated in northern Baffin Bay /9/.

5.7.2 Impact assessment

Mortality of plankton has been observed at close range (within 5 m) of the source of the **seismic** shot /9//26/. The impacts of seismic noise are assessed to have no impact given the size of planktonic populations and their high natural mortality rate.

Discharges may influence planktonic organisms. The discharges associated with the site survey are minor and assessed to be of no measurable impact to water and sediment quality. It is assessed that there will be no impact to plankton.

Table 5-12 Environmental impacts to plankton in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Seismic noise	Minor	Local	Short-term	No impact	High
Discharges	Minor	Local	Short-term	No impact	High

5.8 Benthic flora and fauna

5.8.1 Existing conditions

The knowledge of benthos in Baffin Bay is sparse. Northern Baffin Bay (71-78 °N) was sampled with benthic grab and photography in 2008 /21/. Sampling depths ranged from 0-200 m. In their deepest depth range 150-200 m an average biomass of 175 g wet weight/m^2, and a dominance of polychaetes was recorded.

Figure 5-5 Typical substrate observed during the Baffin Bay drop camera-mediated borehole benthic habitat survey, September 2011 /6/.

In the license blocks, one benthic survey /6/ was done with a drop camera along 11 transects in the northern part of license block Anu, and further north outside the license blocks at depths of 600-750 m. These are the same depths as the planned 2013 site survey. The benthic fauna found by viewing video from 11 transects, consisted of shrimp (most common), brittle stars, sea stars, sea anemones, sponges and soft corals, and some other animal groups. The poor resolution of the pictures made it difficult to discover traces of infauna on the sediment surface, but it is very likely that burrowing polychaetes, molluscs and echinoderms will dominate the infaunal assemblages. The survey also reported strong bottom currents, which makes it likely that the dominant benthos will be filter feeders. The seemingly self-contradictionary combination of strong currents and soft sediment has previously been reported from locations in the Barents Sea /22/.

Single colonies of sponges were discovered in 6 transects in the 2011 survey and no sponge bed aggregations were reported. As observed by Christiansen /25/, sponge beds are present north of Svalbard (78 °N). In case of occurrence of dense sponge beds in the license blocks, further surveying and potential drilling operations should be planned accordingly.

Out of 24 different benthic fauna assemblages defined by Thomson /23/ on the Canadian side of Baffin Bay, nine occurred in Central (72 °N, 70 °E) and Northern (75 °N, 78 °E) Baffin Bay at depths of 500 - 1,088 m and on sand and silt substrates or both. A possibility of finding certain species within each assemblage was calculated, and is presented in Table 5-13. It is considered likely that the same species will occur at the same depths and sediment conditions as the license blocks.

Table 5-13 Short description of some of assemblages of benthic animals found in Central and Northern Baffin Bay /23/. The name gives an indication of the most common species in the particular assemblage.

Assemblage		Sediment	Central/Northern Baffin Bay	Abundance Northern/Central Baffin Bay
Anonyx pacificus	*Amphipod*	Silt	Northern/Central	Rare
Ophiura sarsi	*Brittle star*	Sand	Northern/Central	Common
Ctenodiscus	*Sea star*	Sand/Silt	Northern/Central	Common
Praxillura-Golfingia	*Polychaete - Sipunculid*	Sand/Silt	Northern/Central	Abundant
Lumbrineris - Acsidia	*Polychaete - Sea squirt*	Sand	Northern/Central	Rare
Nereis zonata	*Polychaete*	Silt	Northern/Central	Common/Abundant
Aglaophamus - Asychis	*Polychaetes*	Sand/Silt	Northern/Central	Abundant/Abundant
Samythella	*Polychaete*	Sand	Northern/Central	Abundant
Polyphysia crossa	*Polychaete*	Silt	Central	Abundant

Cold water coral (*Lophelia* sp.) reefs have been discovered in the Davis Strait south of Baffin Bay. It is considered unlikely that reefs will be found in the license blocks as the water temperatures here (1° C) are below the typical temperature range for cold waters corals (4-12° C) /24/.

5.8.2 Impact assessment

This impact assessment is based on the assumption that currents and sediment composition at the survey sites are similar to that found in the 20112 survey /6/. Impacts are summarized in table 6-13.

Grab- and boxcorer sampling, ROV usage and deployment of anchors will **disturb the seabed** by upwhirling. Upwhirled sediments might be carried downstream and fall down on the sea bed elsewhere, where they might resettle and cover epi- and infaunal organisms. Unless the ROV is settled on the seabed and is propelled forward, the amounts of upwhirled sediments will be local and short-term. The impact of resedimentation on benthic fauna is assessed to be negligible.

Removal of soft sediments by grab- or box corer sampler will leave a shallow depression in the sea bed. It may take several years before such depressions are refilled by natural sedimentation, but they will fairly quickly be recolonized. Thus impacts on faunal composition and abundance are negligible.

The deployment of steel weights as mooring for buoys will crush benthic animals directly hit. Some soft bottom benthos can regenerate body parts, but species that have hard calcareous skeletons, like clams or corals, are sensitive to crushing. The area of impact is quite small (1 m^2 per weight) and so the overall impacts of crushing will expectedly be negligible. It is planned to leave the steel weights at the seabed when the buoys are removed. The steel weights represent a permanent hard substrate in what is expected to be a soft bottom benthic community. This will give hard bottom benthos the opportunity to colonize the new substrate, and thus alter the local faunal composition on the spot. Fish, crustaceans and other animals often are attracted to such hard bottom structures in a monotonous soft sediment seabed landscape, where they may find both food and shelter. However, the overall assessment is that leaving the steel weights will have a negligible impact on the seabed fauna.

Recolonization of benthic habitats depend on the type of habitat, the growth rate of the fauna, the geographic extent of the impacted area and the presence of a pool of sexually mature individuals to recruit from. In cold waters fauna normally grow very slow and recolonization back to original species/size composition generally takes longer than further south.

Discharges of grey water and treated black water can lead to increased organic sedimentation. This can lead to changes of species composition and growth in the benthic fauna as a result of increased food availability. However, the release of fine particular material in a stream of freshwater will sink very slowly towards the seabed, and at 600 – 700 m depth, it will be spread over a large area and is not expected to cause any measurable impact on benthos.

Very few studies have been done to determine the impacts of **seismic** and sonar on sessile an in-faunal benthos. Christian et al. /26/ reported that close range seismic sound emission (2 m range) on snow crab eggs had impacts on larval development and settlement. But as the seismic survey and sonar is performed more than 600 m away from the sea bed, it is assessed that there will be no impact to benthic fauna.

Table 5-14 Environmental impacts to benthic fauna in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Seabed disturbance (upwhirling /resedimentation)	Minor	Local	Short-term	Negligible	High
Anchoring	Minor	Local	Permanent	Negligible	High
Discharges -> Increased organic downfall	Minor	Local	Short-term	No impact	High
Seismic noise	-	-	-	No impact	High

5.8.3 Mitigating measures

Deployment of anchors for buoys at the same place as grab samples/box corer has been taken, ensures a minimum of disturbed area on the seabed. A careful and slow approach of equipment to the seabed also minimizes the amount of sediments being temporarily suspended within the water column.

5.8.4 Residual impacts

As the mitigating measures are limited, the residual impacts of the survey activity to benthos are considered the same as the impacts expected before considering any mitigating measures.

5.9 Fish and shellfish

5.9.1 Existing conditions

The fish fauna of Baffin Bay is not well known, and limited specific knowledge from the actual survey area is available. The fish and shellfish fauna of Baffin Bay include populations of several species. According to Jørgensen /27/, at depths below app. 500 m, the Greenland halibut is the dominant species, while species like lumpfish, spotted wolffish, polar cod, capelin, greenland cod, atlantic cod, northern shrimp, snow crab and several species of sculpins, skates and rays also occur in the area. The key species are described below based on the SEIA /9/, the 2012 EIA /6/, and references therein.

The **Greenland halibut** (*Reinhardtius hippoglossoides*) is a circumpolar deep-water, semi-pelagic flatfish that inhabits depths of ~400–2,000 m. It spends most of its life on the bottom, but moves into the water column to feed. Off west Greenland, the Greenland halibut spawn at depths >1,000 m south of 67 °N. The eggs and larvae drift northward and the larvae subsequently settle in the shallower waters of the banks.

In the Northwest Atlantic, the **lumpfish** (*Cyclopterus lumpus*) is distributed from Greenland south to Chesapeake Bay. Lumpfish spend most of the year in deep, offshore waters, but in spring and early summer, typically May–June, they seek shallow coastal waters to spawn. The eggs are attached to the substrate at shallow waters, and the female migrate back to deeper

water immediately after spawning, leaving the male to guard the clumps of eggs for 6 – 8 weeks. The northern distribution limit of lumpfish in Baffin Bay is at 72–75°N.

The **spotted wolffish** (*Anarhichas minor*) occurs in the Arctic Ocean and on both sides of the North Atlantic from Labrador to the Barents Sea. Off West Greenland, it is found as far north as Upernavik and sporadically to Thule. It is found offshore in cold, deep water, usually <5°C at 50–800 m depths. Wolffish prefer coarse sand and sand/shell bottom with rocky areas nearby for shelter and spawning. The species does not form large schools and migrations are local and limited.

The **polar cod** (*Boreogadus saida*), known elsewhere as arctic cod, is a pelagic or semi-pelagic species with a circumpolar arctic distribution. It can form large aggregations, often deep in the water column or near the bottom on the shelf. It also occurs in coastal waters and is often associated with sea ice, in crevices and holes in the ice. Polar cod spawn large buoyant eggs in ice-covered waters in November–February, and the eggs incubate under the ice until larvae hatch in late spring when the ice starts to melt. The polar cod is an important forage species in the arctic marine food web as a key prey for many marine mammals and seabird species.

The **capelin** (*Mallotus villosus*) is a small, pelagic, schooling fish. It is a cold-water species that occurs widely in the northern Hemisphere. In the Disko Bay area, capelins spawn in huge numbers in spring in the subtidal zone along beaches and low rocky coasts. Capelin occur only in the southernmost part of the Baffin Bay, with an approximate northern distribution limit at 72–75°N.

Greenland cod (uvak, *Gadus ogac*) and **Atlantic cod** (*Gadus morhua*) are both found in coastal and open waters of Baffin Bay. The Greenland cod is a coastal/shallow water stationary species of limited commercial value, while the Atlantic cod historically has been an important fishery resource to Greenland. After two decades of virtual absence from west Greenland waters, the Atlantic cod stock during the latest years has reappeared in both coastal and offshore waters off west Greenland. However, the species hardly ranges as far north as the survey area.

The **northern shrimp** (*Pandalus borealis*) occurs all along the on the West Greenland continental shelf from Cape Farewell to ~74°N. It typically occurs in waters 100–600 m deep, mainly on the outer slopes and banks. Although northern shrimp are considered bottom dwellers, they migrate vertically at night and sometimes during the day to feed on the small planktonic organisms in the upper water column. The shrimp larvae are planktonic for 3–4 months, drifting passively with the currents. Shrimp larvae are generally more abundant in waters <200 m deep. Important areas for shrimp larval development are the slopes of the banks, on the banks, and the shelf break. By the end of their first year, most northern shrimp have settled to the seafloor as juveniles.

The **snow crab** (*Chionoecetes opilio*) occurs over a broad depth range in the northwest Atlantic from Greenland south to the Gulf of Maine. Snow crabs are patchily distributed along the west coast of Greenland in coastal areas and fjords, typically at 180–400 m depths /10/. Large males are most common on mud or mud/sand, whereas smaller crabs are common on harder substrates. The snow crab life cycle include larval hatching in the spring, followed by a 12–15 week planktonic period during which the larvae develop through various stages before settling to the sea bottom. Benthic juveniles of both sexes moult frequently. At ~4 years of age, they become sexually mature.

Iceland scallops (*Chlamys islandica*) are generally found inshore and on banks at 20–60 m depths where current velocity is relatively high /10/. The West Greenland populations are generally found in coastal areas. The Iceland scallop lives on the surface of hard substrates, rarely on soft, muddy bottoms. In West Greenland, the largest aggregations are found in the Nuuk area, where most of the direct fishery has taken place. In offshore areas there are only low concentrations of generally small scallops and large quantities of empty scallop shells, suggesting that offshore populations were once more abundant than they are currently.

5.9.2 Impact assessment

Potential impacts to fish are assessed in this section, based on the potential project impacts summarized in section 5.2. Please note that potential impacts to fisheries are assessed in section 5.13.

Noise from site survey has been assessed based on the modelled sound levels and criteria for behavioural and physiological response to underwater noise. There is little information available on the hearing abilities of species of particular relevance for the license blocks; Atlantic cod and Atlantic herring therefore serve as models for other fish species. The upper cut-off frequency of hearing in herring is expected to be the maximum upper cut-off frequency for all fish in the area.

Impacts to fish pertain to physical damage and behavioural changes. Fish behaviour in response to noise is not well understood. Sound pressure levels that may deter some species, may attract others. Physical damages to the hearing apparatus lead to permanent changes in the detection threshold (permanent threshold shift, PTS). This can be caused by the destruction of sensory cells in the inner ear, or by metabolic exhaustion of sensory cells, support cells or even auditory nerve cells. Hearing loss is usually only temporary (temporary threshold shift, TTS) and the fish will regain its original detection abilities after a recovery period. For PTS and TTS the sound intensity is an important factor for the degree of hearing loss, as is the frequency, the exposure duration, and the length of the recovery time.

Fish are highly sensitive to the particle motion of the sound field, and species with no airfilled cavities, such as a swim bladder, cannot detect pressure /28/. Regardless of the presence of air-filled structures, the adequate stimulus for the fish auditory system at frequencies below 100 Hz is particle motion /28/. At higher frequencies the sound pressure impinging on a swim bladder causes it to vibrate, thereby supplying an increase in particle motion stimulating the inner ear. For fish with swim bladder the sound pressure therefore becomes the dominant stimulus. Fish with swim bladders therefore have increased hearing sensitivity at higher frequencies /29/.

The Atlantic cod possesses a swim-bladder but has no special coupling between the swim-bladder and the inner ear. In the Atlantic herring the swim-bladder extends to the inner ear, where it is directly connected /30/. Particle motion measurements of noise sources are rarely made and have not been available for this report. Pressure measurements are therefore used when discussing the impact on fish. The hearing of Atlantic herring has been investigated by Enger /31/, and the hearing of Atlantic cod by several authors /32//33/. The audiograms of these species are shown in Figure 5-6. The thresholds of the audiograms are given in units of sound pressure. Cod can hear up to about 400 Hz, whereas herring can hear up to a few kHz.

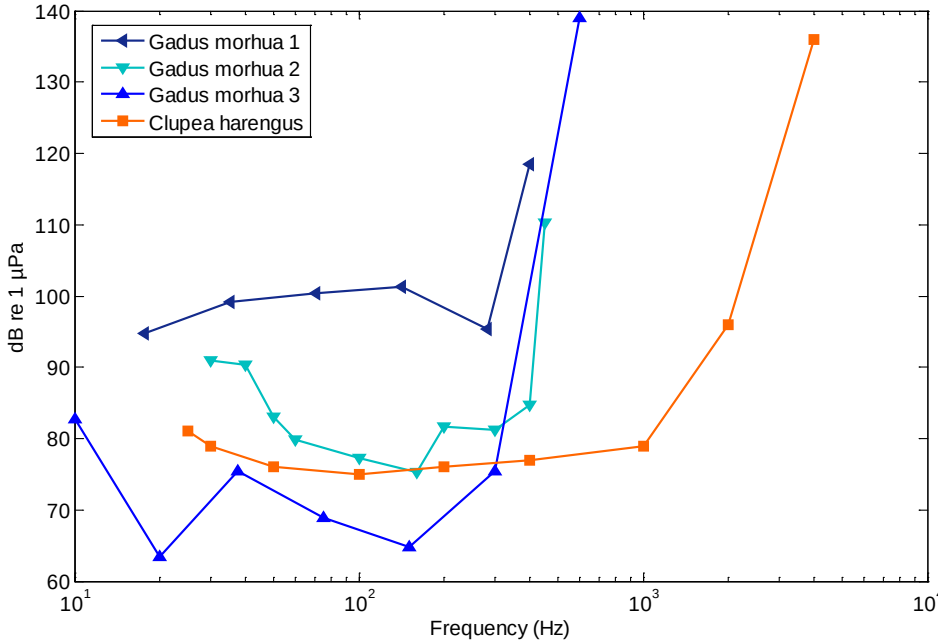

Figure 5-6 Audiogram of Atlantic cod (*Gadus morhus*) and Atlantic herring (*Clupea harengus*) modified from /30//31//32//33/.

Both herring and cod produce sound for communication, but in very different ways. The Atlantic herring produces sound by releasing air bubbles from the anal duct /34/. This creates a pulsed chirp consisting of a series of pulses with centroid frequencies ranging from 3 to 5.1 kHz /34/. Atlantic cod produces sound by contracting muscles associated with the swim-bladder, thereby vibrating the swim-bladder walls. As part of their mating behaviour Atlantic cod produces "grunts". These grunts have frequencies within the range of 50 to 120 Hz /35/. Atlantic cod has also been documented to produce a click sound associated with anti-predator behaviour. These sounds have a peak frequency of 5.95 kHz and a source level of 153 dB re 1µPa.

Fish behaviour in response to noise is not well known. Sound pressure levels that may deter some species, may attract others. One study by Thomsen /36/ does, however, demonstrate initial behavioural response in the Atlantic cod, when exposed to play-back pile-driving noise. Levels that caused response behaviour (= slowing down at onset of sound with overall increased swimming during exposure) were between a peak sound pressure level of 140 and 161 dB re 1 µPa. For both Atlantic cod and Atlantic herring a criterion of a zero-to-peak sound pressure level of 140 dB re 1 µPa will be used as a worst case scenario for the onset of behavioural reaction. Table 5-15 provides an overview of noise exposure criteria for fish used in this assessment.

Table 5-15 Fish noise exposure criteria used in the quantitative assessment.

Effect	Sound type	Sound pressure level /SEL	Source
PTS / Physical damage	Single pulses	206 dB re 1µPa peak	/37/
TTS	Single pules	187 dB re 1µPa^2-s SEL	/37/
Response	Multiple pulses	140 dB re 1µPa peak	/36/

The impact zones of multi-beam echosounders and side-scan sonars vary, as shown in Appendix 2. No frequency weighting has been used for fish.

Table 5-16 Zones of impact for noise sources, defining zones of PTS/TTS and avoidance behaviour in Atlantic cod and Atlantic herring. Data is from Genesis /14/. The line '-' indicates that no record to any range could be found for this sound level in calculations or the model so that effects are not evident. For fish no frequency weighting has been used.

	Effect	Sound pressure level /SEL	Maximum range to threshold location (m)
Multi-beam echosounder	PTS / Physical damage		-
	Response		N/A
Side-scan sonar	PTS / Physical damage		N/A
	Response		N/A
2D HR seismic	PTS / Physical damage	206 dB re 1µPa peak	-
	TTS	187 dB re 1µPa^2-s SEL	-
	Response	140 dB re 1µPa^2·s peak	49,170-58,990

It is clear from the modelling that any physical impacts to fish due to the exposure to single pulses are absent. However, behavioural response in marine fish can occur at ranges of app. 59 km. The differences between the three modelling sites are negligible.

With regards to the *intensity* injury and PTS is defined as a large effect, as the structure and function of the receptor are affected completely inside the affected area. As PTS is not affecting the whole hearing range of the receivers, we have defined this effect as being of medium intensity but of long-term duration. Following this logic, TTS is defined as a medium effect as well

but as it is reversible, it is one of short term duration. Behavioural responses can range from medium to minor, depending on the number of species affected.

The assessment of the different sound levels from all activities on fish species clearly indicates that echosounders and side scan sonar will only lead to minor or moderate impacts. For the 2D seismic surveys TTS can only occur very close to the source (<10 metres). The 2D seismic survey could also lead to avoidance, with behavioural impacts on fish assessed to potentially occur at a distance of 59 km from the source.In any case, the survey will be of only comparably short duration so that effects will be immediate and not of any longer duration. Overall, it can be concluded that the site survey planned for the summer of 2013 will have only moderate noise impacts on the biological environment in Baffin Bay.

Presence of the vessels may pose a potential impact, as noise from vessel engine and propellers may disturb fish. Also the passage of ships through ice infested waters may cause impacts to fish. The overturning of ice-floes has been seen to expose polar cod, living in crevices and hollows in the ice, for predation by gulls and other seabirds following the vessel. The extent of this type of impact is however expected to be negligible, as the survey will take place during the expectedly ice-free period.

Physical **disturbance of seabed** is assessed to have no impact on water and sediment quality. Except from the potential retrieval of individual specimens as part of the samples collected by the box-corer, no impacts to fish assemblages is foreseen.

Discharges of organic **waste** may potentially attract scavenging fish, but no measurable fish aggregations are expected in the license blocks. Temperature increase due to release of wastewater has limited extent and duration and will not cause any influence on marine fish.

Table 5-17 Environmental impacts to fish in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Noise (seismic) TTS	Medium	Local	Short term	Minor	Medium
Noise (seismic) Response	Minor	Regional	Immediate	Moderate	High
Presence of vessels	High	Local	Short-term	Minor	Medium
Disturbance of the seabed	Low	Local	Short-term	No impact	High
Planned discharges	Low	Local	Short-term	No impact	High

5.9.3 Mitigating measures

The proposed site survey in Baffin Bay is constrained to the open-water season. Choosing any other time of the year for doing the survey than the time window planned is not an option.

Mitigating measures are related to number of fixed stations deployed, location and general duration of investigations.

5.9.4 Residual impacts

As the need for and the possibilities to enforce mitigating measures are limited, the residual impacts of the survey activity to fish is considered the same as the impacts expected before considering any mitigating measures.

5.10 Marine mammals

5.10.1 Existing conditions

Marine mammals represent key species in the ecosystem of Baffin Bay in Western Greenland. No resident populations are present in the license areas, which are used by migrating species of marine mammals. Six key species of marine mammals are assessed to potentially occur in the

license blocks; Bowhead whale, Beluga whale, Narwhal, Harbour seal, Ringed seal and Walrus. Pilot whale, hooded seal, sperm whale and minke whale may also be present. These are detailed below, along with the polar bear, with reference to the SEIA for further information /9/. Other occurring species are mentioned briefly and summarized in table 1. Since most species are migratory and have a wide range of distribution, detailed information on presence/absence and seasonality are provided based on the best available information.

During survey activities undertaken in 2011 /75/, marine mammal sightings were recorded for a survey in a larger study area comprising the two license blocks. The results of the survey are presented in Figure 5-7. During the survey, MMSO's observed one unidentified baleen whale, which was observed in the southern license block. In the study area, 16 harp seal sightings (19 individuals), seven ringed seal sightings (9 individuals), and 15 unidentified seal sightings (20 individuals) were observed throughout the study area. Outside the study area, during transit to and from the study area and Nuuk, four minke whales and 78 seals were observed. No other marine mammals (incl. polar bears) were observed at any time during the survey.

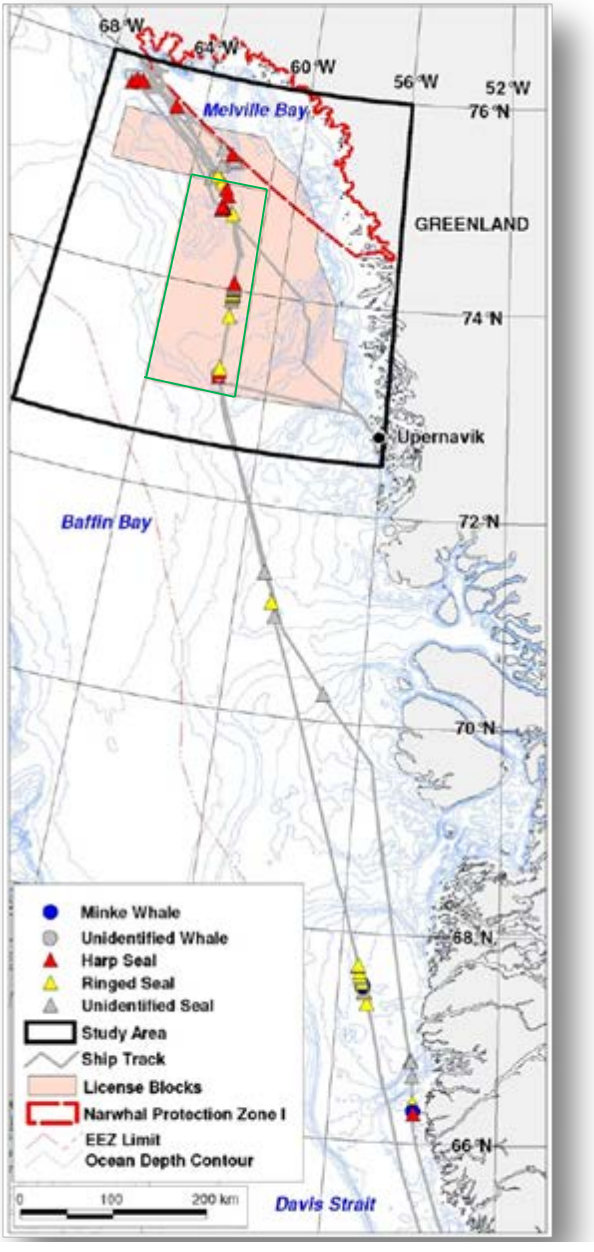

Figure 5-7 Distribution of marine mammal sightings in and around a study area during the August–September 2011. Figure derived from /75/. The license blocks relevant to this EIA are highlighted in green.

During survey activities in 2012, marine mammal sightings were undertaken for a survey in Baffin Bay (including the two license blocks). The survey included seven vessels, and preliminary results include both Baffin Bay as well as transit from Newfoundland, Nuuk and Upernavik.

Preliminary results (unpublished, results provided by Shell) of the 2012 MMSO activities in Baffin Bay show that the sightings included numerous seals, primarily harp, ringed and hooded seals, but also bearded and harbour seals. Most whales were observed during transit to and from the survey area, with sightings of sperm whale, minke whale and sei whale within the license blocks. In addition, a single polar bear was spotted within the two license blocks.

Table 5-18 Preliminary results of the MMSO activities during 2012 survey

Species	All observations		In license blocks	
	No. of animals	No. of observations	No. of animals	No. of observations
Harp Seal	1404	556	907	451
Unidentified seal	230	205	191	170
Long-finned pilot whale	167	14	56	3
Ringed seal	119	117	109	107
Hooded Seal	89	86	78	77
White-beaked dolphin	26	7	4	1
Sperm whale	20	15	16	13
Humpback whale	18	4		
Fin whale	17	14	3	2
Minke whale	15	12	3	3
Bearded seal	14	13	13	12
Sei Whale	14	5		
Large whale	12	12	3	3
Harbour porpoise	9	4		
Unidentified whale	8	5		
Fin/Sei whale	5	2		
Bottlenose Whale	4	2	1	1
Harbour seal	2	1	2	1
Hooded/bearded seal	1	1	1	1
Polar bear	1	1	1	1
Grand Total	**2175**	**1076**	**1388**	**846**

5.10.1.1 Whales

In the license blocks, the sea ice cover throughout the spring months represents a constraint to the presence of these animals, which will only reach such locations once the ice retreats /9/. The narwhal and beluga whale are specialised inhabitants of the Arctic and can be found in Baffin Bay year round /9/. Other species are generally only present in the area during ice-free periods of the summer.

The **narwhal** (*Monodon monoceros*) has very specific habitat requirements, ranging between 70 ^{o}N and 80 ^{o}N throughout Arctic and North Atlantic waters. Populations from Canada and West Greenland have high site fidelity to the winter pack ice of Davis Strait and Baffin Bay in regions along the continental slope.

Two narwhal populations are found near the license blocks during summer, one in Melville Bay and another in Inglefield Bredning further north. However, only the Melville Bay population is found in the license blocks, and they are found in the northeast corner of the area during summer. Migration through the license blocks appears to follow the 1,000-m contour southward. Narwhals from the Canadian High Arctic can migrate through the License blocks as early as late September–early October, and narwhals from Melville Bay migrate south from mid-October to mid-December, depending on the year /6/.

Narwhal feed primarily on Greenland halibut, together with other fish, squid and shrimp - mainly in the winter at deep water and possibly at or near the bottom /40/. Narwhals breed only once every 3 years between March and May with calves being born during the following summer.

Protection zones for narwhal are described in section 5.11.

The **beluga whale** (*Delphinapterus leucas*) is distributed throughout arctic and sub-arctic waters /41/. During the winter months, belugas congregate around areas of loose ice, feeding from the polynyas. They inhabit coastal waters, estuaries, shelf breaks, and deep basins during the summer months. In 2006 the abundance of belugas in West Greenland was estimated to 10,595 individuals, and concentrations of whales were mostly located in Disko Bay on the northern shore of Store Hellefisk Bank as well as along the eastern edge of the pack ice covering Baffin Bay and Davis Strait /6/. Approximately 30% of the Eastern Canadian high Arctic/Baffin Bay Beluga stock migrates to West Greenland for overwintering /39/.

Belugas that occur in and near the license blocks during part of the year are found in Lancaster Sound, Barrow Strait, Peel Sound, and Baffin Bay during the ice-free period /9/. Migration routes are primarily along the coast and through near shore waters, so few whales are expected in the license blocks at any time of year except perhaps in April–June, during the spring migration, when some animals travel through loose pack ice in offshore areas /6/.

Belugas acquire most of their annual food during the winter, which makes them particularly sensitive during this time of the year. They feed on polar cod and other fish but also squid and shrimps. Mating season is mainly between late February to early April, with calves being born between May and July in latitudes after a gestation period of over a year /9/.

During the winter **bowhead whales** (*Balaena mysticetus*) are observed in areas near the ice edge and in areas of unconsolidated pack ice. In the Baffin Bay-Davis Strait, bowhead whales move out of the summering areas as the ice forms during autumn towards the open water near the ice edge off West Greenland and eastern Baffin Island /42/. Bowhead whales seasonally use the eastern parts of Baffin Bay for feeding and undertake migrations /9/.

Although this species feeds mostly during the winter months at particular feeding grounds, it may also feed opportunistically during the spring migration. Their diet is based on crustacean zooplankton (copepods), epibenthic organisms, and some benthic organisms. Mating usually occurs during late winter and early spring. Soon after the calves are born (between April and June, but mostly in May), spring migration takes place.

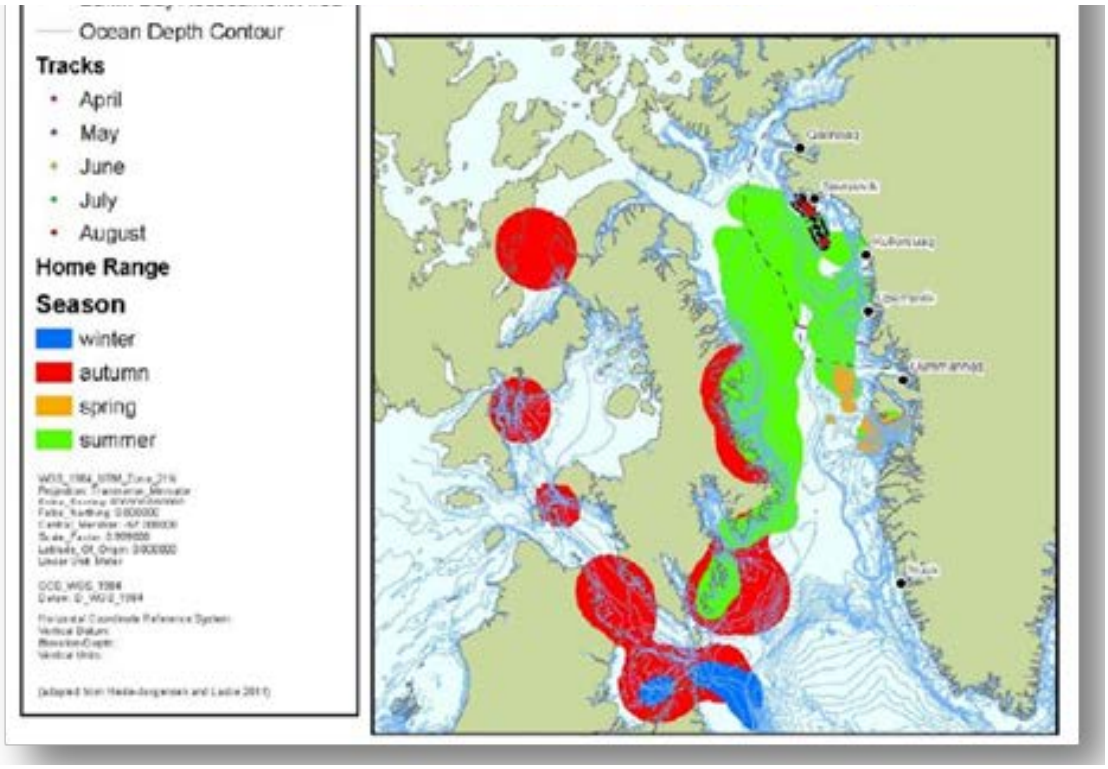

Figure 5-8 Seasonal home range distributions of bowhead whales in 2009. Adapted from 2012 EIA /6/.

Other whales may also be encountered in Baffin Bay. Minke whales (*Balaenoptera acutorostrata*) are common within Baffin Bay, but there is no knowledge on specific, important areas for this species within West Greenland. Sei whales (*Balaenoptera borealis*), fin whales (*Balaenoptera physalus*), humpback whales (*Megaptera novaegliae*) and blue whales (Balaenoptera musculus) can also occur in the south of Baffin Bay from June to November. Pilot whale (*Globicephala melas*), white-beaked dolphin (*Lagenorhynchus albirostris*) and bottlenose whale (*Hyperodon ampullatus*) may also occur /9/. Killer whales (*Orcinus orca*) could be encountered occasionally in the license blocks, mainly during the summer /6/.

5.10.1.2 Walrus and seals

The walrus and several species of seals occur in the Baffin Bay. Ringed seals and bearded seals are residents and more or less dependent on the sea ice , while harp seals and hooded seals are migrants and are present only when there is open water /9/.

Walruses (*Odobenus rosmarus*) breed in the Arctic pack ice during winter. Often walruses haul out on land or ice floes in groups of up to several thousand individuals. Five of the presumed eight sub-populations of Atlantic walrus are in Western and three are in Eastern Greenland. Walrus generally have an affinity for shallow water areas where they feed on a variety of benthic invertebrates, although they occasionally make dives to maximum 200–250 m depth, which makes most of the license blocks too deep for this species. However, a limited number of walruses spend the winter in leads and cracks between the land-fast ice and the moving pack ice in the license blocks. Moreover, there seems to be an unknown number of walruses that use this location as a migration corridor during spring and perhaps also autumn /9/.

A protection zone for walrus is are found north of the license blocks, see section 5.11. Protection period in the walrus protection zone is from 1 Oct. to 31 May.

The **ringed seal** (*Pusa hispida*) is the most common seal in the Arctic and is abundant in Baffin Bay. The ringed seal use sea ice exclusively as their breeding, moulting and resting habitat, rarely, if ever, coming onto land. Average densities of ringed seals on fast ice as well as on consolidated pack ice in the Baffin Bay area vary between 1.3–2 seals/km^2 in June. This density range can probably be applied to a large part of Baffin Bay /9/.

Females give birth in the spring (March to May). Moulting occurs from mid-May to mid-July. Then, the animals spend a considerable amount of time hauled out on ice at the edge of the permanent pack ice, or on remnant land-fast ice along coastlines. During this period, feeding activity is at its minimum. Outside the breeding and moulting seasons, this species is distributed in waters of nearly any depth. Ringed seals prey on small animals, and preferred prey tends to be schooling fish species, mainly polar cod.

The **bearded seal** (*Erignathus barbatus*) is a large seal, usually associated with the sea ice and is considered resident in Baffin Bay. They feed on fish and benthic invertebrates found in waters down to 100 m depth. Bearded seals make breathing holes where the ice stays relatively thin and they either winter in reoccurring leads and polynyas or they follow the pulse of the expanding and shrinking sea ice. Birth takes place in April–May on drifting ice or near ice edges with access to open water. Bearded seals are present throughout the Baffin where suitable habitats are available, and no particular important areas for the species are known /9/.

The **harp seal** (*Pagophylus groenlandicus*) is present in the license blocks from late-June to November. Harp seals are caught in large numbers in the coastal area near the license blocks, particularly in the late summer and autumn months. Their offshore prey is unknown, but amphipods are likely to be important. Around 10 % of the population of the seals from the West Atlantic population (estimated at about 6 million individuals) spend the summer and autumn foraging in Davis Strait and Baffin Bay /9/.

Hooded seal (*Cystophora cristata*) is a large migratory seal that does not breed in East Baffin Bay. It occurs late in the open-water season (July to October) and usually in offshore waters. It is a deep diver, feeding regularly below 500 m. The adult seals migrate to Davis Strait and Baffin Bay during the end of July /9/.

5.10.1.3 Polar bear

The **polar bear** (*Ursus maritimus*) relies almost entirely on the marine sea ice environment throughout their life cycle, and are known to travel great distances through the Arctic region generally on drifting oceanic ice floes, in search of food. Polar bears spend over 50 % of their time hunting for food, and their diet mainly consists of ringed and bearded seals /40/. Breeding occurs in March to May, and birth is generally thought to occur from late November to mid-January /38/.

Baffin Bay is an important polar bear habitat during autumn, winter and spring. When the central Baffin Bay field of consolidated pack ice disappears during spring and summer the polar bears either use eastern Baffin Island or the Melville Bay area as a summer retreat /9/.

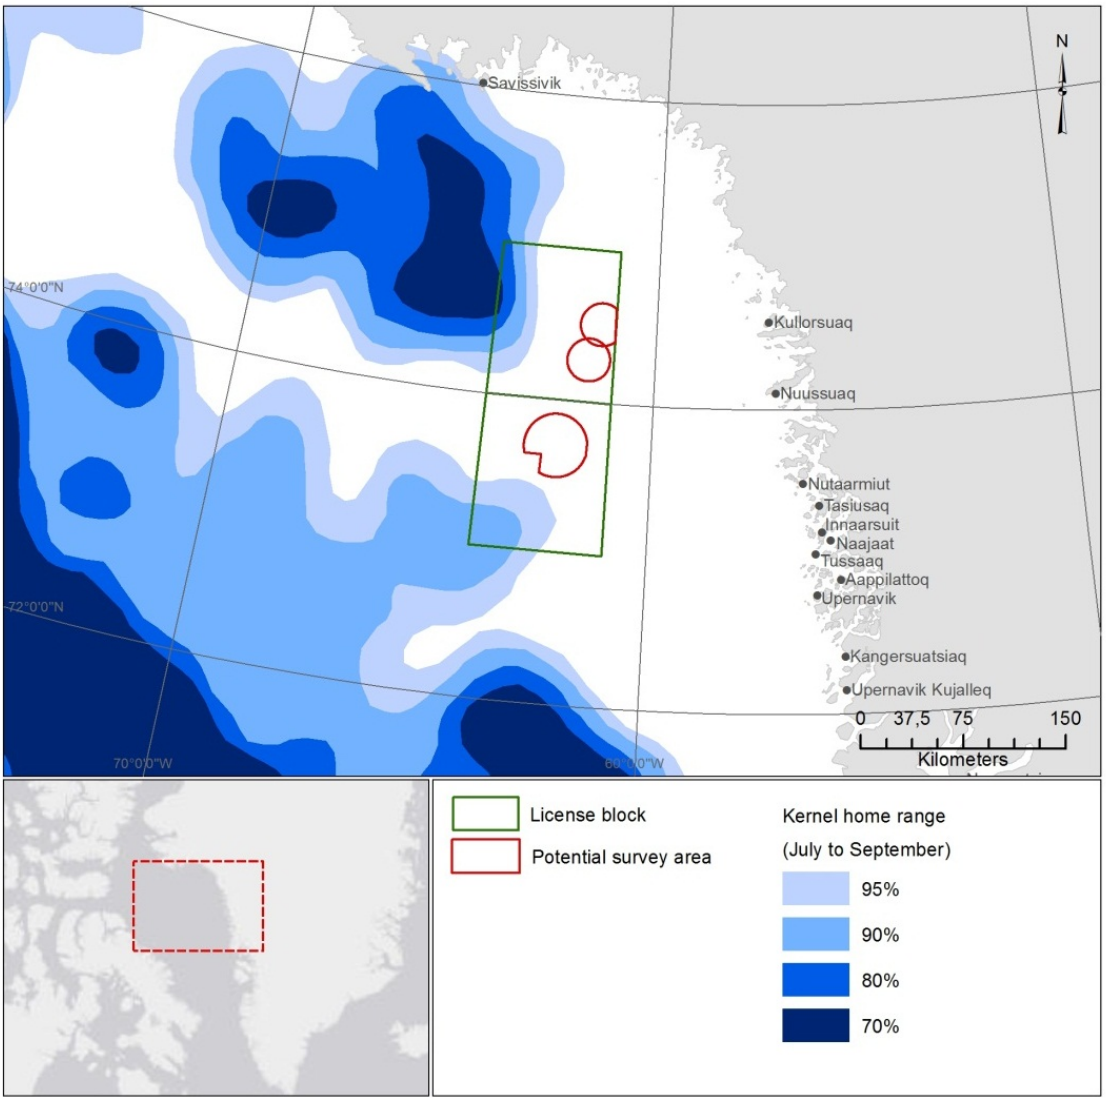

Figure 5-9 Polar bear Kernel home range (July to September). Adapted from Perry et al. (2011)

5.10.1.4 Overview of marine mammals

Table 5-19 provides an overview of marine mammals occurring in Baffin Bay, their main habitat and their red list status.

Table 5-19 Overview of marine mammals occurring in the strategic assessment area, their conservation status and hunting status (adapted from /9/).*LC=Least concern, DD=data deficiency, NT=not threatened, VU=vulnerable, ENCR=critically endangeres.

	Period of occurrence in Baffin Bay	Main Habitat	Biological activity	Greenland Red List status*	Distribution in the Baffin Bay SEIA area
Baleen Whales					
Minke Whale (*Balaenoptera acutorostrata*)	April-November	Coastal waters and banks	Feeding only. Winter breeding grounds are unknown	LC	Common in south
Fin Whale (*Balaenopetara physalus*)	June-October	Edge of banks and coastal waters	Feeding only	LC	Occasionally in south
Blue Whale (*Balaenoptera musculus*)	July-October	Edge of banks	Feeding only	DD	Occasionally in south

Humpback Whale (*Megaptera novaeangliae*)	June-November	Edge of banks and coastal waters	Feeding only	LC	Abundant in south
Sei Whale (*Balaenoptera borealis*)	June-October	Offshore	Uncertain	DD	Occasionally in south
Bowhead whale (*Balaena mysticetus)*	February-June	Pack ice and marginal ice zone	Feeding	NT	Locally abundant migrant and winter visitor
Toothed whales					
Narwhal (*Monodon monoceros*)	Whole year (mostly in summer and mid-seasons)	Winter: Edge of banks, deep water. Summer: Fjords, coastal waters. Migrants along 1000 m contour	Feeding November-March. Breeding March-May. Calfs are born in Summer/Fall	CR	Abundant summer and winter as a migrant
Beluga whale (*Delphinapterus leucas*)	October-November, April-June	Banks	Feeding November-March. Breeding February-late April. Calfs are born May-July	CR	Abundant migrant
Killer whale (*Orcinus orca*)	June-August	Ubiquitous	Feeding. Breeding in Summer.	NA	Occasional
Long-finned pilot whale (*Globicephala melas)*	June-August	Deep waters	Feeding. Breeding in Summer.	LC	Occasional in south
White-beaked dolphin (*Lagenorhynchus albirostris*)	Summer	Shelf waters	Feeding. Lack of breeding data	NA	Occasional in south
Sperm Whale (*Physeter macrocephalus*)	May-November	Deep waters	Feeding only	NA	Unknown
Harbour porpoise (*Phocoena phocoena*)	April-November	Coastal waters	Feeding only	DD	Only in south
Northern bottelnose whale (*Hyperodon ampullatus*)	Summer	Deep waters	Feeding only	NA/DD	Unknown
Walrus and seals					
Walrus (*Odobenus rosmarus*)	Whole year	Polynyas, mariginal ice zone, shallow water	Feeding. Breeding in winter. Pups are born mid-April to mid-June	ENCR	Migrants from adjacent areas
Ringed Seal (*Pusa hispida*)	Whole year	Waters with ice	Feeding. Breeding in late April-early May. Pups are born March-May	LC	Common and widespread

Hooded Seal (*Cystophora cristata*)	June-October	Mainly deep waters	Feeding only	LC	Common and widespread
Bearded Seal (*Erignathus barbatus*)	Whole year	Waters with ice	Feeding. Pups are born mid-March to mid-April	DD	Numerous
Harp Seal (*Pagophilus groenlandicus*)	June-October	Whole area	Feeding only	LC	Widespread and abundant
Carnivores					
Polar Bear (*Ursus maritimus*)	Whole year	Drift ice and ice edges	Breeding in March-May. Birth in late November - mid January	VU	Common, mainly with ice

5.10.2 Impact assessment

Potential project impacts are detailed in section 5.2. Of relevance to marine mammals are the potential project impacts noise, light and physical disturbance. Each potential project impact is assessed in relation to marine mammals, with focus on focal species of mammals in the area; bowhead whale, beluga whale, narwhal, harbour seal, ringed seal, walrus and polar bear. Similar impacts are expected for other marine mammal species.

Noise from seismic activities is considered the main potential impact to marine mammals. Marine mammals are sensitive to the pressure component of a sound field. Species-specific information on sensitivity is presented below, followed by an impact assessment.

Generally, the effect of noise on marine mammals can be divided into four broad categories that largely depend on the individual's proximity to the sound source:

- Detection
- Masking
- Behavioural changes
- Physical damages

It is important to note that the limits of each zone of impact are not sharp, and that there is a large overlap between the different zones. Behavioural changes, masking and detection also critically depend on the background noise level and all impacts depend on the age, sex and general physiological and behavioural states of the animals /60/.

Detection ranges depend on background noise levels which are unknown in this case. They are of great importance when discussing masking effects, but masking is not a directly relevant issue for pulsed sounds such as those used in the site survey /15/. This impact assessment is therefore restricted to physical damages and behavioural changes.

Physical damages to the hearing apparatus lead to permanent changes in the animals' detection threshold (permanent threshold shift, PTS). This can be caused by the destruction of sensory cells in the inner ear, or by metabolic exhaustion of sensory cells, support cells or even auditory nerve cells. Hearing loss is usually only temporary (temporary threshold shift, TTS) and the animal will regain its original detection abilities after a recovery period, but in prolonged exposures, where the ear is exposed to TTS inducing sound pressure levels before it has had time to recover, TTS may build, and a TTS of 50 dB or more will often result in permanent damage /62/. For PTS and TTS the sound intensity is an important factor for the degree of hearing loss, as is the frequency, the exposure duration, and the length of the recovery time.

Changes in behaviour are inherently difficult to evaluate. They range from very strong reactions, such as panic or flight, to more moderate reactions where the animal may orient itself towards the sound or move slowly away. However, the animals' reaction may vary greatly depending on season, behavioural state, age, sex, as well as the intensity, frequency and time structure of the

sound causing behavioural changes. According to Miller et al. /92/ (also see Southall /60/) exposures to sound pressure levels between 130 dB re 1 µPa and 150 dB re 1µPa from airgun array pulses induced behavioural reactions in wild beluga whales. Yet, not all individuals showed a reaction with no apparent changes in behaviour at received levels of well above 150 dB re 1µPa (see Miller et al. /92/). The EIA for the 2012 3D seismic survey /6/) used an exposure criterion of a sound pressure level of 150 dB re 1 µPa for behavioural impacts. Recent research on impulsive pile driving sounds /90//91/ and airgun pulses /89/ indicates that the harbour porpoise - a species particularly sensitive to acoustic disturbance – exhibit avoidance behaviour at received sound exposure levels of around 140 dB re 1 $\mu Pa^2 \cdot s$. This criterion will be used for all three species of cetacean for the 2D seismic surveys. Since for the echosunders and sidescan sonars, only sound pressure levels were available, we used a received sound d pressure level of 140 dB re 1 µPa as the criteria for behavioural reaction for these sources following a precautionary approach. Avoidance behaviour in ringed seals and bearded seals is induced at exposure levels exceeding sound pressure levels of 190 dB re 1µPa /60/. This criterion is also assumed for walruses.

Beluga whales and narwhals both use echolocation to navigate and forage. They emit broadband echo-location clicks of very short duration /46/. Beluga whale clicks are centred around 100-115 kHz and have peak-to-peak source levels up to 225 dB re 1µPa /46/. Narwhal clicks have peak frequency at 20 and 40 kHz, and the maximal peak-to-peak source level measured is 218 dB re 1µPa /47/. The hearing sensitivity has been investigated in the beluga whale both behaviourally and using ABR (latest by Finneran et al /48/) and the audiogram is presented in Figure 5-10. An audiogram shows the hearing sensitivity with frequency on the x-axis and sound level on the y-axis. In general, audiograms have a U – shape with the areas of best sensitivity at the lowest values. Hearing in the narwhal has not yet been investigated, but in the following it is assumed to be comparable to that of a beluga whale. Beluga whale hearing becomes increasingly directional with higher frequencies. This increase in hearing directionality at the frequencies relevant for echo-location improves their echo-location capabilities by making them less susceptible to background noise and clutter echoes (i.e. returning echoes from other objects than the intended target) /49/. Directional hearing at higher frequencies is also expected for narwhals, as it has been demonstrated in other echo-location toothed whales as well /50/. Beluga whales and narwhals both use a variety of different sounds for communication. They use clicks, but also sound with significantly lower frequencies known as whistles and pulsed calls. Beluga whale communication sounds range from 260 Hz to 20 kHz, but with dominant frequencies from 1 to 8.3 kHz /11//51/. Narwhal communication sounds are lower in frequency ranging from 400 Hz to 14.5 kHz /52/. Lowering the frequency content causes the sound to be emitted more omnidirectionally which could be advantageous when communicating in a group.

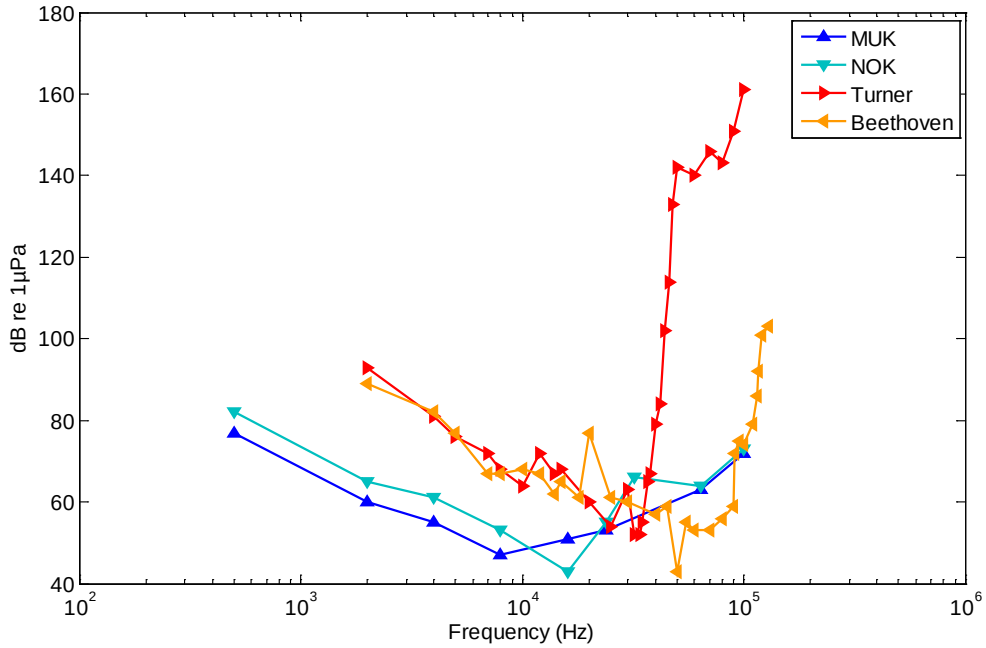

Figure 5-10 Audiogram of four beluga whales. Beethoven and Turner are modified from Ridgway et al. 2001. MUK and NOK are modified from /48/.

The hearing in baleen whales requires further investigation. However, anatomical studies of the inner ear in the northern right whale (*Eubalaena glacialis*), a close relative of the bowhead whale, suggest that this species has a hearing range from 10 Hz to 22 kHz /53/. This study is the only study to directly infer the complete hearing range of any baleen whale. Baleen whales are known to produce low frequency, high intensity calls for communication. Bowhead whales produce songs as well as calls, with a total frequency range for both types of sound being between 25 Hz and 2.6 kHz /54/.

Pinnipeds, such as walruses, bearded seals and ringed seals, are amphibious animals, and their hearing has evolved to function in both air and water, two acoustically very different media. The underwater hearing sensitivity of a male walrus can be seen in Figure 5-11. The hearing sensitivity has only been studied in a few species of pinnipeds. Studies of hearing thresholds for ringed seals and bearded seals are currently underway. However, the underwater hearing sensitivity of the harbour seal has been studied extensively (Figure 5-11) /56//57//58/ and will serve as a model for the underwater hearing sensitivity of ringed and bearded seals. The hearing thresholds of harbour seals are generally recommended to be used as a conservative estimate of the hearing thresholds for species where the hearing has not been investigated /60/. Pinnipeds produce a wide range of communication calls both over and underwater. Underwater calls are mainly associated with courtship behaviour and territoriality and are often produced by males /59/. Walruses produce underwater sounds with frequencies mainly below 1-2 kHz and may contain significant energy even at 10 Hz /11/. Bearded seals produce a variety of mating sounds with frequencies ranging from 200 Hz to 22 kHz /59/, and ringed seals produce sounds with frequency contents between 400 Hz and 16 kHz /11/.

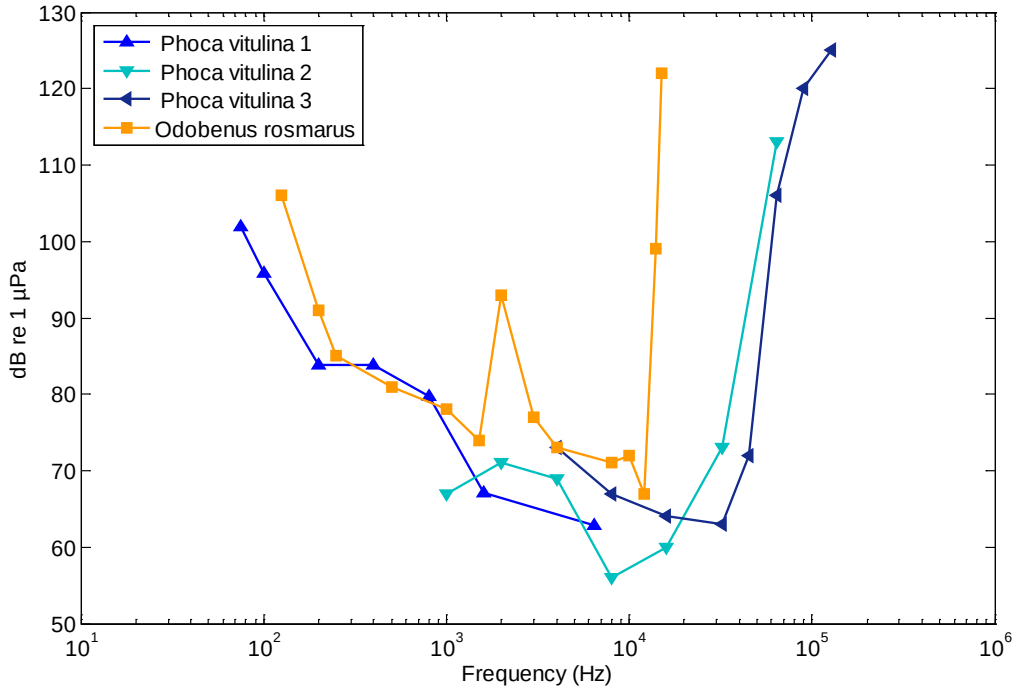

Figure 5-11 Audiogram of harbour seal and walrus. Harbour seal (*Phoca vitulina* 1-3) are modified from /56/ /57/ /58/. Walrus (*Odobenus rosamrus* is modified from Kastelein /55/.

For the quantitative assessment of impact ranges for behaviour and injury, criteria for marine mammals have been derived from a variety of sources (see /61//60/). The NMFS criteria /61/ are part of the US regulation (except, to our knowledge, the behaviour criteria). The NMFS criteria are based on the assumption that received levels that are lower than these criteria will not injure animals or impair their hearing abilities but higher received levels may have some effects. We have interpreted these criteria as the onset of TTS also noting the relatively low thresholds. Applicable are also the initial scientific recommendations on marine mammal noise exposure criteria as developed by a group of US experts /60/.

PTS has not been measured in any cetaceans, but Southall /60/ proposes peak sound pressure levels of 230 dB re 1µPa and SEL levels of 198 dB re: 1 µPa2-s (Mlf) as criteria both for single and multiple pulses. A study by Finneran /63/ measured TTS in a beluga whale when exposed to a single sound pulse from a seismic watergun. The TTS limit was at a peak-to-peak sound pressure level of 226 dB re 1 µPa (recovery to within 2 dB of the original hearing sensitivity after 4 min). A similar criterion for PTS and TTS will be assumed for narwhals and bowhead whales.

Table 5-20 provides an overview of noise exposure criteria for marine mammals used in this assessment. Studies of hearing thresholds for ringed seals and bearded seals are currently underway. However, the underwater hearing sensitivity of the harbour seal has been studied extensively and served as a model for the underwater hearing sensitivity of ringed and bearded seals.

Table 5-20 Marine mammal noise exposure criteria used in the quantitative assessment.

Effect	Taxa	Sound type	Sound pressure level / SEL	Source
Start of hearing effects - TTS	Cetaceans	Airgun pulses	180 dB re 1µPa	/61/
Start of hearing effects - TTS	Pinnipeds	Airgun pulses	190 dB re 1µPa	/61/
PTS	Cetaceans (Beluga, narwhal, bowhead whale)	Single - multiple pulse	230 dB re 1µPa peak	/60/
PTS	Cetaceans (Beluga, narwhal, bowhead whale)	Single - multiple pulse	SEL 198 dB re 1µPa^2-s (M_{lf}, M_{mf}, M_{hf})	/60/
PTS	Pinnipeds (in water)	Single pulse - multiple pulse	218 dB re 1µPa peak	/60/
PTS	Pinnipeds (in water)	Single pulse - multiple pulse	SEL 186 dB re 1µPa^2-s (M_{lf}, M_{mf}, M_{hf})	/60/
TTS	Cetaceans (Beluga, narwhal, bowhead whale)	Single pulses	224 dB re 1µPa peak	/60/
TTS	Cetaceans (Beluga, narwhal, bowhead whale)	Single pulses	183 dB re 1µPa^2-s SEL (M_{lf}, M_{mf}, M_{hf})	/60/
TTS	Pinnipeds (in water)	Single pulses	212 dB re 1µPa peak	/60/
TTS	Pinnipeds (in water)	Single pulses	171 dB re 1µPa^2-s SEL (M_{pw})	/60/
TTS	Pinnipeds in water	Single pulses	226 dB re 1µPa peak to peak	/63/
Onset of response	Cetaceans (Beluga, narwhal, bowhead whale)	Multiple pulses 2 D seismic / echosounder / side scan sonar	140 dB re 1µPa^2·s / 140 dB re 1µPa	/60//89/
Response	Seals	Multiple pulses	190 dB re 1µPa	/60/

Using the criteria for injury and avoidance behaviour described above, zones of impact for the different sound sources are calculated from the M-weighted sound pressure source levels. Mammals generally do not hear equally well over their entire range of hearing. Towards the lower and upper cut-off frequencies the perceived loudness becomes less than what is predicted from the audiogram /64/. This discrepancy in perceived loudness can be compensated by applying an equal-loudness filter. Southall /60/ developed equal-loudness filters for the different marine mammal groups, and in the following this M-weighting will be applied for the evaluation of noise impact where possible. More details about M-weighting are given in the acoustic modelling report.

Little information is available regarding the power spectra of the sound sources investigated here. In the following it is assumed that the main sound energy is centred at 95 kHz for the multi-beam echosounder and 100-110 kHz for the side-scan sonar. This gives a conservative estimate of zones of impact. These frequency ranges, and M-weighted source levels, are used to calculate the distance between the source and the injury and behavioural response threshold locations /60/.

- The assumed M-weighted sound pressure levels (SPL_M) for a multi-beam echosounder are 221 dB re 1 µPa for mid-frequency cetaceans and 215 dB re 1 µPa for pinnipeds, the frequency range of the echosounder is outside the hearing range of low-frequency cetaceans.
- The SPL_M for the side-scan sonar is very similar to the multi-beam echo-sounders with 222 dB re 1 µPa for mid-frequency cetaceans and 217 dB re 1 µPa for pinnipeds.

The zones of impact for the equipment associated with multi-beam echosounder and side scan sonar are collected in Table 5-21.

Table 5-21 Zones of impact for a multi-beam echosounder and side scan sonar, defining zones of PTS/TTS and avoidance behaviour in the beluga whale, narwhal, bowhead whale, walrus, bearded seal, ringed seal, Atlantic cod and Atlantic herring. Data on multi-beam echosounder noise is from Genesis /14/. ([a] criteria from the National Marine Fisheries Service). The line '-' indicates that no record to any range could be found for this sound level in calculations or the model so that effects are not evident.

	Effect	Sound pressure level /SEL	Maximum range to threshold location (m)
Multi-beam echosounder	PTS	Cetaceans (narwhal and beluga)	-
	PTS	Pinnipeds (in water)	-
	TTS	Cetaceans (narwhal and beluga)[a]	85
	TTS	Pinnipeds (in water)[a]	20
	Response	Cetaceans (Beluga, narwhal)	350 - 800
	Response	Seals (bearded and ringed seal)	20 – 250
Side-scan sonar	PTS	Cetaceans (narwhal, beluga and bowhead whale)	-
	PTS	Pinnipeds (in water)	-
	TTS	Cetaceans (narwhal and beluga)[a]	90
	TTS	Pinnipeds (bearded and ringed seal)[a]	35
	Response	Cetaceans (Beluga, narwhal)	350 - 800
	Response	Seals (bearded and ringed seal)	35 – 350

For the assessment of the impact zones from the 2D high resolution survey, numerical modelling of underwater noise was applied, as detailed in Appendix 2.

The results of the modelling for the seismic survey are shown in Table 5-22. The spatial dimension of the underwater noise field is assessed for single shots and a survey undertaken over 24 h, see Appendix 2. It is very clear from the assessment that any physical impacts due to the exposure to single pulses are restricted to very close ranges from the source. Behavioural response in cetaceans is assessed to occur at distances of up to 6 km from the source. The differences between the sites are negligible.

Table 5-22 Zones of impact for the 2D high resolution seismic survey (see detailed results in the acoustic modelling report, Appendix 2)

Effect	Taxa	Sound pressure level / SEL	Maximum range to threshold location 1,2 and 3 (m)
Start of hearing effects - TTS	Cetaceans	180 dB re 1µPa	70-80
Start of hearing effects - TTS	Pinnipeds	190 dB re 1µPa	-40
PTS	Cetaceans (Beluga, narwhal, bowhead whale)	230 dB re 1µPa peak	-
PTS	Cetaceans (Beluga, narwhal, bowhead whale)	SEL 198 dB re 1µPa^2-s (M_{lf}, M_{mf}, M_{hf})	-
PTS	Pinnipeds (in water)	218 dB re 1µPa peak	-
PTS	Pinnipeds (in water)	SEL 186 dB re 1µPa^2-s (M_{lf}, M_{mf}, M_{hf})	-
TTS	Cetaceans (Beluga, narwhal, bowhead whale)	224 dB re 1µPa peak	-
TTS	Cetaceans (Beluga, narwhal, bowhead whale)	183 dB re 1µPa^2-s SEL (M_{lf}, M_{mf}, M_{hf})	30 M_{lf}
TTS	Pinnipeds (in water)	212 dB re 1µPa peak	-
TTS	Pinnipeds (in water)	171 dB re 1µPa^2-s SEL (M_{pw})	50-
TTS	Pinnipeds in water	226 dB re 1µPa peak to peak	-
Response	Cetaceans (Beluga, narwhal, bowhead whale)	160 dB re 1µPa	230-250
Response	Cetaceans (beluga, narwhal, bowhead whale	140 dB re 1µPa	5,800 – 6,090
Response	Seals	190 dB re 1µPa	40-

With regards to the intensity we define injury and PTS as being a large effect, as the structure and function of the receptor are affected completely, and structure and function are lost completely inside the affected area. As PTS is not affecting the whole hearing range of the receivers, we have defined this effect as being of medium intensity but of long-term duration. Following this logic, TTS is defined as a medium effect as well but as it is reversible, it is one of short term duration. Behavioural responses can range from medium to minor, depending on the number of species affected.

Applying the NMFS criteria, echosounders are predicted to lead to TTS in narwhal and beluga at 85 m from the source and in pinnipeds at distances of 10 m from the source. Behavioural effects are expected from 20 m (seals) to 800 m (narwhal and beluga). The impact ranges for the side scan sonar are TTS at 90 m in belugas and narwhals and at 35 m in pinnipeds. Behavioural responses are expected at a maximum range of 800 m (narwhal). Seals are much less affected with behaviour to be expected up to 320 m from the source.

For the 2D high resolution surveys TTS will be limited to areas close to the source (80 m in cetaceans and 40 m for pinnipeds). The onset of behavioural response can be expected in all three cetacean species at distances of up to 6 km from the source with little difference between the sites. For seals, behavioural responses are only expected at close ranges (40 m).

The results of the impact assessment are summarized in Table 5-24. As can be seen, the effects of noise on marine organisms are directly coupled to the activities. With the exception of the bowhead whale, TTS may be induced at relatively short distances. If noise inter-pulse intervals are shorter than the TTS recovery periods, TTS may accumulate and could potentially result in PTS (see also assessment of cumulative SEL levels for the 2D seismic survey). However, for the received levels, duty cycles and exposure times of interest here, the possibility of PTS to occur based on multiple exposures is very low. Once survey activities subside, physical effects should disappear within a few days. Behavioural effects could result in animals leaving the area for longer periods, but should return to normal within a few months at most.

Estimates of number of individuals and percentage of population assessed to be physiologically or behaviourally impacted from single airgun pulses have been assessed. The assessment has been made based on the population and density estimates performed for the 2012 EIA for seismic activities in the two license blocks /6/ and the zones of impact assessed in the acoustic modelling. A summary of the calculations is presented in Appendix 3. As presented in Table 5-23, the numbers of affected individuals are very low, with less than 1 individual potentially impacted for all species.

Table 5-23 Estimates of number of individuals assessed to be physiologically or behaviourally impacted impacted from single airgun pulses. A summary of the calculations are presented in Appendix 3.

	Animals assessed to be physiologically impacted (TTS)		Animals assessed to be behaviourally impacted	
	Individuals[1]	Percentage of population[2]	Individuals[1]	Percentage of population[2]
Ringed seal	$7.0 * 10^{-3}$	$3.1 * 10^{-6}$	$7.0 * 10^{-3}$	$3.1 * 10^{-6}$
Narwhale (offshore)	$5.2 * 10^{-5}$	$3.5 * 10^{-7}$	0.29	$2.0 * 10^{-3}$
Beluga whale (summer)		$1.2 * 10^{-7}$		$6.9 * 10^{-4}$
Beluga whale (fall)		$1,2 * 10^{-6}$		$6,9 * 10^{-3}$
Bowhead whale		$1,2 * 10^{-5}$		$6,9 * 10^{-2}$
Walrus		$3,1 * 10^{-6}$		$3,1 * 10^{-6}$

Presence of vessels may contribute to the animals' habituation to human activities. However, limited interaction between the site survey and marine mammals in the area is expected. Marine mammal responses to vessels often include changes in general activity (e.g., from resting or feeding, to active avoidance), changes in surfacing-respiration-dive cycles, and changes in speed and direction of movement. Behavioural reactions tend to be reduced when animals are actively involved in a specific activity such as feeding or socializing, as reviewed by Richardson /43/. Whales react most noticeably to erratically moving vessels with varying engine speeds and gear changes, and to vessels in active pursuit. In general, large baleen whales are more susceptible to strikes than smaller toothed whales. A description of the response of the six focal species is presented in the following.

Belugas and Narwhals' response to vessels during ice-free seasons are variable, ranging from tolerance to avoidance. The response of belugas and narwhals appears to be dependent on the type of vessel, its speed and course, the whales' activity, and their previous exposure to industrial activity. According to Finley /44/narwhal and belugas' sensitivity to vessel presence in Lancaster Sound declined after repeated exposures. Narwhals revealed more subtle reactions to oncoming vessels than belugas, generally by slowing-down their movements or remaining motionless near the ice edge, as reviewed in /6/. In Baffin Bay few belugas are expected to occur, and narwhals from Melville Bay are not expected to be present in the license blocks. Thus, it is not expected that belugas and narwhals will be majorly exposed to vessels to cause disturbance or mortality. Marine mammal observers will also be onboard, mitigating this impact. Given the planned mitigation measures, it is assessed that the impacts will be negligible.

Bowhead whales seem to show avoidance reactions to approaching vessels at distances of 4 km or greater /43/. When vessels travel slowly, bowhead whales are often more tolerant, showing little or no reaction. Furthermore, bowhead whales engaged in social interactions or mating may be less responsive than other bowhead whales /6/. Bowhead whales may be encountered in the license blocks during the site survey period. However, the planned timeline for this project does

not overlap with major feeding or breeding periods/areas of the whales. Thus, it is believed that if encountered, a bowhead whale would be able to avoid the vessels and prevent ship strikes. Marine mammal observers will also be onboard, mitigating this impact. For this site survey it is thus assessed that the operations involved may not impact bowhead whales.

A study on walrus /45/ showed that when hauled-out on ice, the behavioural reaction of walruses depends mainly on vessel distance and speed. In addition, walrus respond at greater distances when a vessel approached from downwind as compared with upwind, and that this species shows less reaction in water than on ice. Thus, collisions between vessels and walrus do not seem to be of concern. However, walrus are not expected to be present in the license blocks, which is too deep for them to feed >200m. For this current study, walrus vessel avoidance reactions in water are expected to be localized and short-term.

There are few studies on pinnipeds' behavioural reaction to vessels. Hauled-out ringed seals often show short-term escape reactions to approaching ships within 250–500 m /38/. It seems that when in water seals are less responsive to approaching vessels than when on ice, and may even lead to curious behaviour /6/.

Polar bears have no natural predators and, given their position at the top of the food web, it is very sensitive to changes in the arctic marine ecosystem. According to Fay et al. (1984), most polar bears seem to be little affected by vessel presence, although different behavioural reactions have been documented. Generally, the responses tend to be short-term and usually described as avoidance by walking, running, or swimming away. However, other bears may not show any reactions at all /6/). Mothers with cubs are expected to be more protective and cautious, especially when more than one cub is present. Encounters between vessels and swimming polar bears are very unlikely, as few polar bears sightings are expected during the proposed period of the site survey.

Seabed disturbance and changes in food availability are assessed in previous sections. Certain marine mammals that may occur in the license blocks are known to feed on benthic animals, particularly the narwhal, beluga, bearded seal and walrus. However, belugas and narwhals acquire most of their dietary requirements during the winter, feeding very little, if at all, during the summer. Being located offshore at water depths of 400 – 800 meters, survey sites are at depths deeper than the feeding range for walrus, which is able to dive no deeper than c. 200 meters. Any seabed disturbances related to the site survey are considered to be of no influence to marine mammals.

The previous sections have assessed the impacts of the survey activities to fish and lover trophic ecosystem levels. No or minor impacts to neither pelagic crustaceans nor pelagic fish are expected. Based on this, it is assessed that there will be no impacts to whale or seal feeding in the license blocks, caused by alterations of the distributions of prey items.

The presence of moored hydrographic stations has some probability of causing **entanglement** of mammals. This may prove fatal to an individual becoming entangled. The moored equipment of the survey are expected to consist of ropes/wires being stretched between anchor, measuring instruments and flotation buoys all the time the equipment is deployed. Avoiding slack and loose piles of floating rope will reduces the risk of accidental entanglement of whales or seals. There is a low risk of entanglement and ship collision to individuals, and the overall impact is assessed to be none.

Navigational and deck- working **lights** used to illuminate working areas, are sources of artificial light being spread into the environment. Light may attract plankton and fish, serving as prey for marine mammals. However, planned activities are scheduled to take place within a time window from July to October, during which daylight dwindles, and illumination gradually becomes needed. It is assessed that light from the site survey on marine mammals will have no measurable impact.

Table 5-24 Environmental impacts to marine mammals in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Noise (MBES) TTS	Medium	Local	Short-term	Moderate	Medium
Noise (MBES) Response	Medium	Local	Short-term	Minor	Medium
Noise (SSS) TTS	Medium	Local	Short-term	Moderate	Medium
Noise (SSS) Response	Medium	Local	Short-term	Minor	Medium
Noise (seismic) TTS	Medium	Local	Short term	Minor	Medium
Noise (seismic) Response	Medium	Regional	Immediate	Moderate	Medium
Presence of vessels	Medium	Local	Short-term	Minor	Low
Seabed disturbance and changed food availability	-	-	-	No impact	High
Entanglement in mooring	Low	Local	Short	No impact	High
Light	Low	Local	Short	No impact	High

5.10.3 Mitigating measures

The mitigation measures applied are:

- Marine mammal observers, ensuring that the survey is delayed if animals are observed
- Soft start procedure gradually increasing the sound energy to provide time for mammals to leave the area
- Observations of a safety zone (500 m) where the survey is stopped if animals are observed
- Passive acoustic monitoring system, enabling registration of marine mammals under adverse weather conditions.

The site survey is undertaken applying the mitigating measures outlined above and no further mitigating measures are expected.

5.10.4 Residual impact

The planned mitigating measures would effectively alleviate the risk of temporary threshold shift. However, the measures would not be mitigating to behavioural impacts as ranges are larger and animals cannot be visually observed at these distances.

The residual impact to marine mammals is thus assessed to be minor.

5.11 Protected areas

5.11.1 Existing conditions

Figure 5-12 show protected areas in or near the license blocks. There are no Ramsar-areas, important bird areas (IBA) or areas protected according to the Greenland Nature Protection Law (Melville Bay reserve and Bird Protection areas) within the license blocks.

The license blocks are situated in a seismic protection zone for narwhal, appointed as a migration corridor (narwhal zone II). The protection zone is the fall migration habitat where the narwhals (and beluga whales) are present from 15 October at least until 1 Dec. Seismic activities in narwhal zone II shall be confined to a minimum in the protection period.

Narwhal zone I is the summer habitat, where narwhals are present when the sea ice melts in summer until fall migration (1 June to 15 Oct). Beluga whales also occur in this area from 1 October. The shortest distance from survey areas to the seismic protection zone for narwhal summer habitat is approximately 40 km.

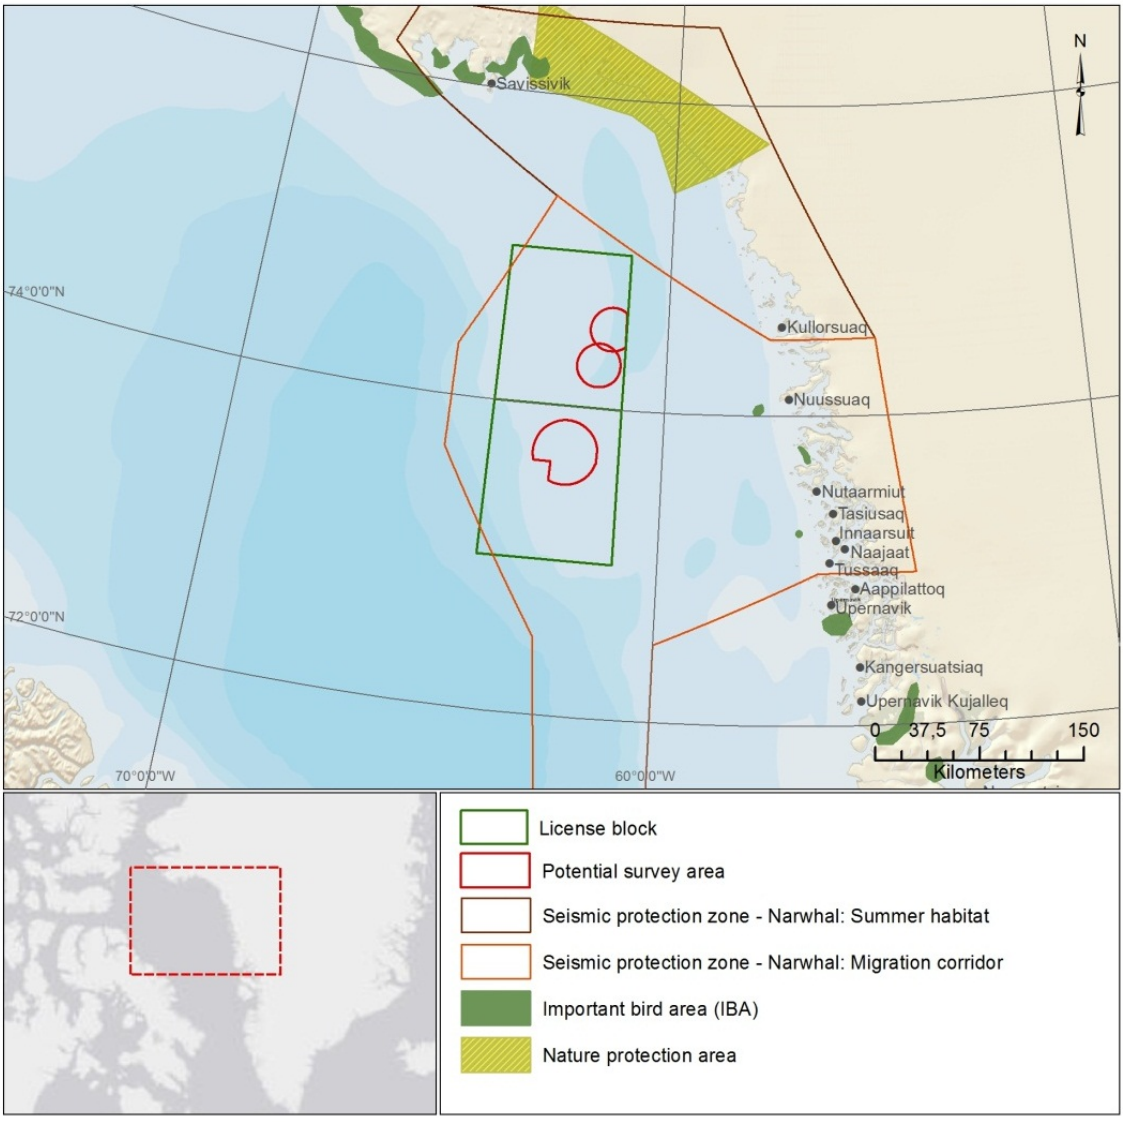

Figure 5-12 Protected and important areas in and near the license blocks.

5.11.2 Impact assessment

The license blocks only overlap with one type of protection zone: seismic protection zone for narwhal. The protection zone is the fall migration habitat where the narwhals (and beluga whales) are present from 15 October at least until 1 Dec. As there is no overlap between the site survey and the protection period, it is assessed that there will be no impacts to protected areas.

Table 5-25 Environmental impacts to protected areas in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
None				No	High

5.12 Seabirds

5.12.1 Existing conditions

The highly productive waters off Northwest Greenland combined with suitable breeding habitats along the shores attract millions of seabirds during the open water season (May – September). Most of the seabirds found in the region are migratory and only visit the area during the breeding period. The birds arrive from early May from the eastern Canadian Arctic, eastern Canada, northeaster United States, Western Europe, and the south Atlantic, and many species aggregate in large breeding colonies containing several million pairs /9/.

Besides being an important breeding area, the Baffin Bay area supports large numbers of migrating birds traveling through the area to and from breeding sites in the northern parts of Canada and Greenland /9/.

The seabirds play an important role in the High Arctic ecosystem. Because they breed on land and forage at sea, they transport nutrients across the biogeographic boundary between the highly productive sea and the relatively low productive terrestrial ecosystem. Thus, colonial seabirds play a key role in fertilizing and sustaining the terrestrial ecosystem /66//67/.

Many seabird species in the Baffin Bay area are fish consumers and prey on species such as capelin, sand eel and polar cod. Other species live on benthic invertebrates or support the fish diet with large zooplankton species (copepods, amphipods and krill) /9/. Little auks are specialized on a planktivorous diet and prey entirely on zooplankton throughout the breeding period /69/. The different diet preferences are reflected in the foraging behaviour (foraging range, diving depth, timing etc.). Some species (such as guillemots) show diving depths of more than 100 meters while other species (such as little auks) mainly feed in the surface waters (10-50 meters) /70//9/. Some species are forced on long distance foraging trips due to unsustainable local foraging options and may travel more than 100 kilometres to locate suitable prey /9/.

The most numerous seabird species in High Arctic is the little auk (*Alle alle*) /84/. Estimated 80 % of the total world population (corresponding to 33 million birds) breeds in the Avanersuaq (Thule) district of Northwest Greenland /71/. In addition, the majority of the Greenland breeding population of Brünnich's Guillemots (*Uria lomvia*) breed in the area /9/. Also, northern fulmar (*Fulmarus glacialis*) and Black-legged kittiwake (*Rissa triactyla*) are common in Baffin Bay /9/. A list of important species for the area is presented in
Table 5-26.

Among the species found in the Baffin Bay area, several are of conservational concern and included on the Greenland Red List and/or are of national or international importance. The conservational status for selected species is presented in Table 5-26.

Table 5-26 Overview of selected seabird species found offshore in the Baffin Bay area. List modified from /9/.

Species	Greenland Red List status	National responsibility species*	Importance of Baffin Bay area**
Fulmar (*Fulmarus glacialis*)	Least Concern		High
Red-necked phalarope (*Phalaropus lobatus*)	Least Concern		Low
Red phalarope (*Phalaropus fulicarius*)	Least Concern		Low
Black-legged kittiwake (*Rissa tridactyla*)	Vulnerable		High
Glaucous gull (*Larus hyperboreus*)	Least Concern		Medium
Icelandic gull (*Larus glaucoides*)	Least Concern	Yes	Low
Sabines Gull (*Xema sabini*)	Near Threatened		Low
Ivory gull (*Pagophila eburnean*)	Vulnerable		Medium
Arctic tern (*Sterna paradisaea*)	Near Threatened		High
Atlantic puffin (*Fratercula arctica*)	Near Threatened		High
Brünnich's Guillemot (*Uria lomvia*)	Vulnerable		High
Black guillemot (*Cepphus grylle*)	Least Concern	Yes	High
Razorbill (*Alca torda*)	Least Concern		High
Little auk (*Alle alle*)	Least Concern	Yes	High

*National responsibility species (defined as more than 20 % of the global population in Greenland), species with isolated population in Greenland and species listed as 'Data Deficient' (DD) occurring in the assessment area. Only species which may occur in marine habitats are included.
**Importance of Baffin Bay SEIA area to population (conservation value) indicates the significance of the population occurring within the Baffin Bay assessment area in a national and international context.

On a large scale the general knowledge of seabirds in the area is well known whereas, detailed information of offshore distribution and area utilization is very sparse. Presumably the most important offshore areas include waters with early ice break-up and areas where upwelling events are recurrent /9/. However, a report on marine mammal and seabird surveys conducted during a seismic site survey in 2011 include seabird observation from 65-76° N between August and September /75/. The density of birds ranged from 0.83 birds/km^2 (August, 68–70 °N) to 9.11 birds/km^2 (September, 74–76 °N). The highest densities were observed in the most southerly (65–68 °N) and most northerly (74–76 °N) latitudes of the survey area. A list of species observed from those surveys is presented in Table 5-27.

Table 5-27 Summary of selected bird observations during a seismic site survey off northwest Greenland between 11 August and 18 September 2011, modified from /75/.

Species	Total number (individuals)
Fulmar (*Fulmarus glacialis)*	398
Red-necked phalarope (*Phalaropus lobatus)*	14
Red phalarope (*Phalaropus fulicarius)*	45
Arctic skua (*Stercorarius parasiticus)*	8
Black-legged kittiwake (*Rissa tridactyla)*	398
Glaucous gull (*Larus hyperboreus)*	122
Icelandic gull (*Larus glaucoides)*	1
Sabines Gull (Xema sabini)	1
Ivory gull (*Pagophila eburnean)*	2
Arctic tern (*Sterna paradisaea)*	4
Atlantic puffin *(Fratercula arctica)*	1
Brünnich's Guillemot (*Uria lomvia)*	118
Black guillemot (*Cepphus grylle)*	36
Little auk (*Alle alle)*	1,925
Eiders (*Somateria* spp.)	92

Harlequin duck (*Histrionicus histrionicus)*	1
Gyrfalcon (*Falco rusticolus)*	2
Peregrine falcon (*Falco peregrinus)*	1
Baird's sandpiper (Calidris bairdii)	1
Pomarine skua (*Stercorarius pomarinus)*	10
Long-tailed skua (Stercorarius longicaudus)	16

5.12.2 Impact Assessment

Noise from seismic surveying may negatively affect the seabirds as physical damage caused by sound waves, and may also cause a behavioural response. In addition, the physical presence of the seismic vessel itself may affect the birds, as reviewed in /9/.

Very little is known about under water hearing in diving seabirds and information on effects from underwater sound on birds are sparse. During a seismic exploration programme in Davis Strait, no behavioural response or mortality of the seabirds was detected /72/. Observations from operation seismic vessels in the Irish Sea also did not reveal any behavioural response of seabirds to the survey activities /73/. Birds diving very close (a few meters) to an air gun array, may potentially suffer damage to the auditory system. However, birds have the ability to regenerate the sensory cells in the inner ear and a possible hearing impairment, would thus be temporary.

Due to the highly mobile nature of birds, they are generally not considered to be sensitive to seismic surveys. This is supported by the few studies carried out this far that did not find any mortality impact or behavioural response of birds foraging close to a seismic survey vessel /73/.

Based on the available information there is no indications that noise related to seismic surveys (seismic sounds and vessel noise) causes any substantial disturbing or injuring impacts on seabirds.

Light and illumination may attract birds when it is dark or under certain weather conditions (such as snow or fog). Birds may fly into parts of the ships infrastructure and get injured, killed or stranded. Stranded and injured birds are often not capable to leave the vessel again and in most cases, they die from exposure, dehydration, or starvation over hours or days.

In Greenland, the problem especially relates to eiders. More that hundred individuals have been reported killed on a single ship in a study by Merkel and Johansen /74/. However, the study was carried out off southwest Greenland and collision was mainly reported for periods of darkness and snowy weather. During the ice free period there is constant light in the Baffin Bay area (a phenomenon called midnight sun). The sun will set in early September, when most birds have left the area. The potential negative impacts from ship lighting are thus expected to be limited to periods after August, and it is assessed that there will be no severe impacts to seabirds.

Table 5-28 Environmental impacts to seabirds in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Noise	Minor	Local	Short-term	No impacts	High
Light	Minor	Local	Short-term	No impacts	High

5.13 Commercial and recreational fishery

5.13.1 Existing conditions

The commercial fisheries make up nearly 90 % of the Greenlandic export and play a vital role in the country's national economy. The offshore commercial fishery is carried out by a fleet of modern stern-trawler. This is mobile and flexible vessels, being able to exploit resources over vast areas, and as such less dependent on specific fishing areas (except for limitations related to seabed topography vs. trawling).

The survey area is located some 100 km from the coast, which is out of the normal range for many coastal fishing vessels. The fishing activity in the survey area is expected to be carried out by large, flexible trawlers.

The months from August-October are important months for the commercial fishery, with 40 % of the annual catch caught during three months (see Figure 5-13).

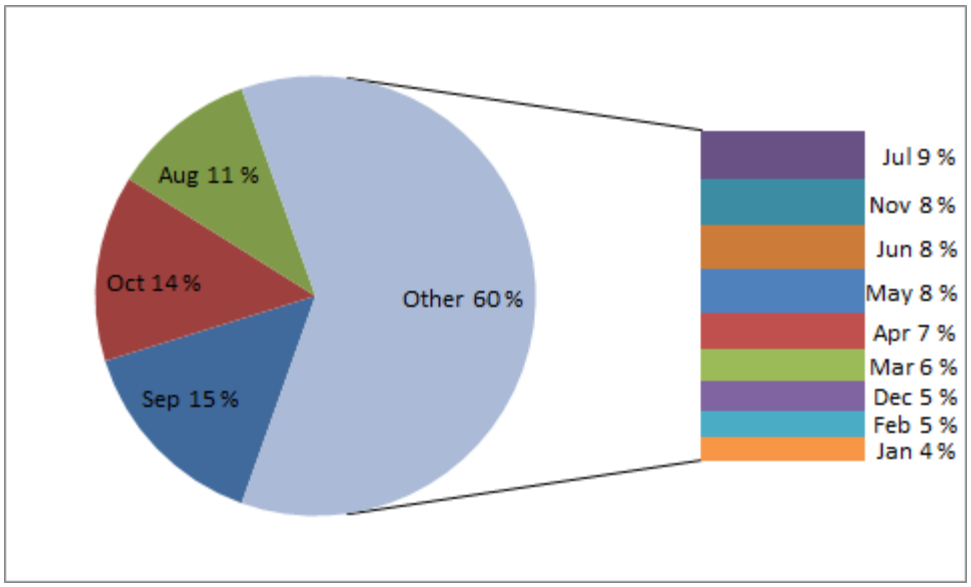

Figure 5-13 Annual variation in yearly landed species for the 2000-2010 in area 1A. The NAFO 1A area covers all west Greenlandic waters from 68˚50' to 78˚ N in the Baffin Bay. Source: www.nafo.int.

Most of the commercially important resources are found south of the survey area, and Baffin Bay only contributes marginally to the total Greenlandic fishery /27/. The recent Baffin Bay SEIA /9/ summarises fishing activity in the area as primarily targeting Greenland halibut, while the shrimp fishery mainly takes place south of the survey area. The general fishery pattern in Baffin Bay can be summarised as being performed by large trawlers registered in Greenland, targeting shrimp and Greenland halibut during autumn (August – October). The distribution of Greenland halibut fishery is shown in Figure 5-14.

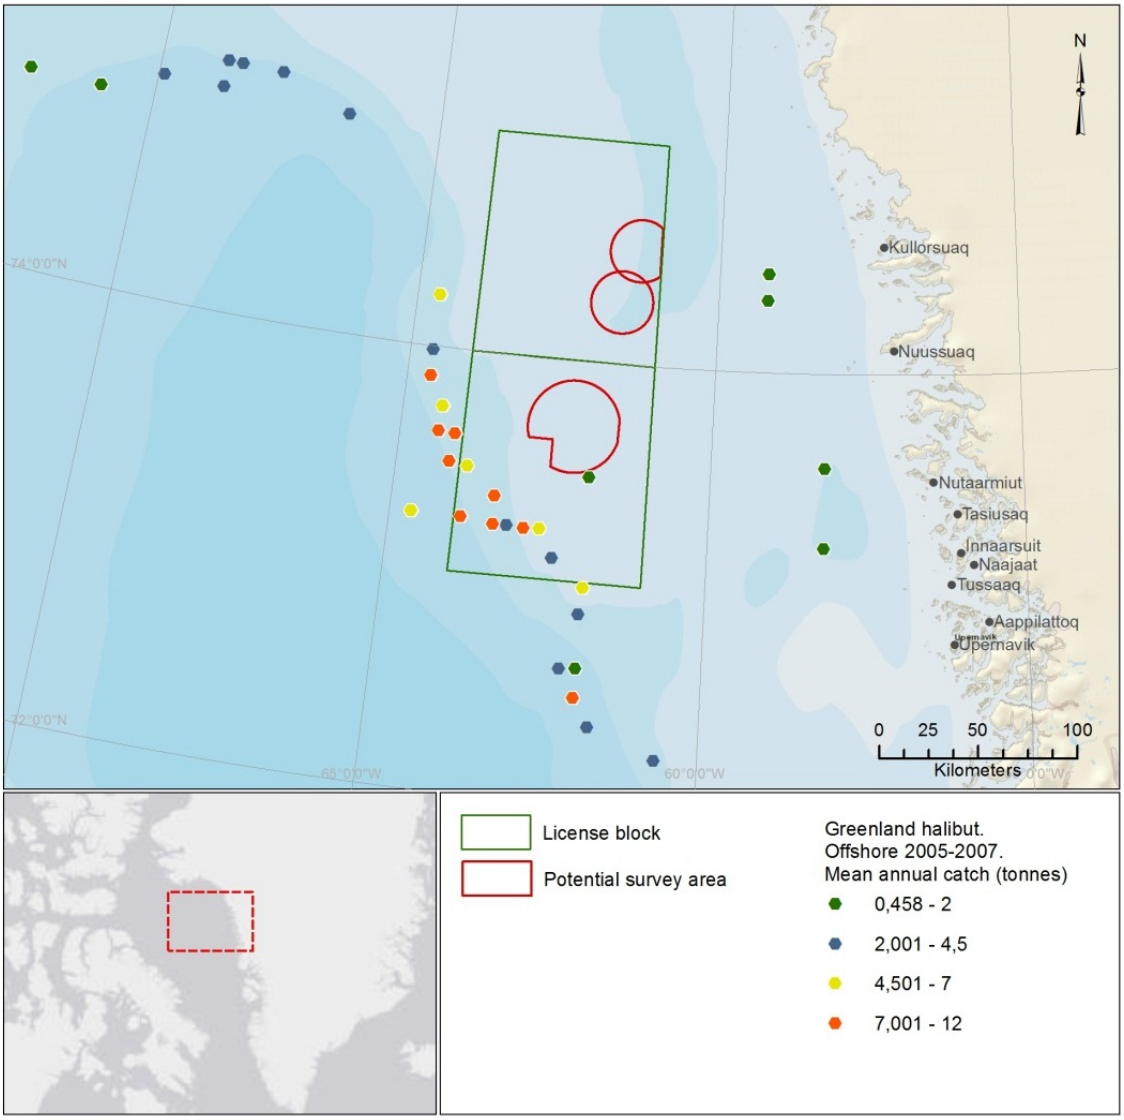

Figure 5-14 Distribution of Greenland offshore halibut fishery and size of landings from the assessment area. Redrawn from /9/

The shrimp population in West Greenland waters is decreasing due to poor recruitment. The catch quotas are decreasing accordingly (from an estimated catch in 2012 of 110 000 tons to a quota recommendation given by Pinngortitalerifiik (Greenland Institute of Natural resources) of 80,000 tonnes in 2013 /76/. This is likely to lead to reduced effort, and less important areas will tend to become even less interesting to the trawling fleet. Historically, the shrimp fishery has taken place south of the survey area, but the shrimp trawlers are flexible and independent of harbour/support facilities, and if ice conditions and catch rates are favourable in the survey area, the trawlers might be fishing in this region.

Greenland halibut is the second important commercial fish resource being harvested in the survey area. This stock seems to be stable, and a total allowable catch (TAC) of approx. 13 000 tons (the same as 2007 - 2012) is expected for 2013 /77/. Reduced availability of shrimp may encourage increased effort in the trawling for Greenland halibut, but it is considered unlikely that the survey area during 2013 will be of particular significance to Greenland halibut fishery. Despite a predicted increase in the population of Atlantic cod off west Greenland, this species has not (yet) increased in numbers sufficient to compensate for dwindling shrimp quotas.

The license blocks are located some 100 km from the coast and far from the major settlements and villages in west Greenland. The area thus is of limited or no interest to the smallest fishing and recreational vessels.

Local fishing and hunting historically form the backbone of Greenlandic household and culture. Greenlandic rural societies traditionally depend on harvesting a broad variety of nature resources, like fish, birds and mammals. Most of the harvested mammals are used for local consumption /self-sustained household and preparing traditional commodities like boots, clothes and works of art. International restrictions in trade of products derived from endangered and threatened mammal species has limited the possibilities for trading this type of commodities, and infrastructure development has reduced the necessity for local communities being self-sustained. However, hunting and fishing is still a very important part of the way of living.

5.13.2 Impact assessment

The most prominent impacts known to occur to fishing, is the operational inconveniences of presence of seismic vessels with limited manoeuvrability, and changes in fish behaviour due to the seismic noise, the latter expressed by avoidance behaviour and paused feeding.

Seismic data acquisition has been proven to influence catch rates of gadoid fishes (haddock and cod) in trawl fisheries in the Barents Sea /78/. This is valid for pelagic and semi pelagic fish with air-filled swim-bladder. Despite spending a significant amount of time in the pelagic /83/, the Greenland halibut has no swim-bladder, and is thus potentially less disturbed by seismic surveys.

The Greenland halibut fishery was in focus in connection with seismic surveys off Lofoten in Norway in 2008 and 2009 /82//79/. However, the expressed concern was merely a result of overlap in time with a strongly regulated fishery and not an indication that this species is particularly sensitive to seismic surveys.

Very limited knowledge exists on seismic impacts to crustaceans. Parry and Gason /80/ is one of the few studies addressing this topic, finding no impacts to lobster fishery

Physical presence of equipment may pose a hindrance to trawling activities. The survey is planned for the ice free period, coinciding with the period in which trawling is possible. None of the survey activities occupy large areas for any prolonged time, but even presence of one single installation (a hydrographic measuring station) in a trawl field is a hindrance requiring attention during trawling. The survey area is not known to be of significance to Greenland halibut trawling to an extent making alternative towing routes/areas less attractive. The current level of knowledge leaves no indications that mooring of instruments at the survey sites will lead to loss of fishing time due to necessary caretaking and avoidance by trawlers. The planned sampling leaves no anchor-mark like changes to the seabed; meaning no impacts to fishery besides the short time physical area occupation during sampling

Impacts from the planned 2013 surveys to fishing are summarised in Table 5-29.

Table 5-29 Environmental impacts to commercial and recreational fishery in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
Noise and presence of vessel (from seismic and vessel operations)	Medium	Regional	Short-term	Minor impact (Limited fishery -> limited extent of impact)	High
Physical disturbance of the seabed	Low	Local	Short-term	No impact	High

Except the considerations made on seismic impacts to fishing, the planned activities of the survey are considered only to pose an insignificant and marginal influence to the expectedly limited fishery of the survey area during July – October 2013. The survey is not expected to cause any influence on the quality of fish and shellfish for human consumption.

5.13.3 Mitigating measures

A site survey of a specific location has limited, if any, possibilities to move the activity to other locations. Spatial mitigating measures to reduce influence on fisheries are thus limited to changes of the order in which the survey locations are visited. This should be considered in dialogue with any fishing vessels operating in the area during the survey.

The planned site survey in Baffin Bay is restricted in time by the heavy ice conditions most of the year. The ice-free time window sets limitations on timing of the survey, as well as trawling, thus overlap with any trawling activity in the area seems likely, given that fishing takes place. Choosing any other time of the year for doing the survey than the time window planned is not an option.

Mitigating measures in terms of order of magnitude of impact is related to number of fixed stations deployed, location and general duration of investigations.

5.13.4 Residual impacts

As the need for and the possibilities to enforce mitigating measures are limited, the residual impacts of the survey activity to fisheries is considered the same as the impacts expected before considering any mitigating measures.

5.14 Maritime traffic

5.14.1 Existing conditions

Maritime traffic in Baffin Bay is primarily fisheries, cargo and cruise ships, the number of which has been increasing in recent years /85/. According to Joint Arctic Command in Nuuk the marine traffic in the area is limited and primarily consists of:

- Cargo ships. The settlements in the Upernavik district received supplies by cargo ships. The cargo ships normally sail along the coast and are not expected in or near the license blocks. Only a very limited number of cargo ships are using the north-west passage.
- Cruise ships. Cruise ships are concentrated in the area near Ilulissant and do normally not sail offshore.
- Fishing vessels. As described in section 5.13, minor halibut fishing is taking place in the southern part of the license blocks and no shrimp fishing is conducted in the license blocks.

The Northwest Passage is the name given to a set of marine routes between the Atlantic and Pacific Ocean, spanning the straits and sounds of the Canadian Archipelago. The passage is a transportation corridor through one massive archipelago until it reaches open, but ice-infested waters in the Baffin Bay (east) and Beaufort Sea (west). Current shipping demand in the Northwest Passage involves up to 22 seasonal trips and occurs during the 100 day navigation season that span from mid-July to the end of October /85/.

5.14.2 Impact assessment

The amount of marine traffic in the license blocks is very limited in the license blocks as the majority of the maritime traffic is nearshore. On this background, it is assessed that the site survey will have no impact on maritime traffic.

Table 5-30 Environmental impacts to maritime traffic in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
-	-	-	-	No impact	High

5.15 Tourism

5.15.1 Existing conditions

The most important asset for the tourist industry is the unspoiled, authentic and pristine nature.

Besides tourists staying in hotels and other accommodation on shore, cruise ships bring an increasing number of tourists to Greenland, with 23,500 visitors in 2011 /85/. The cruise ships focus on the coastal zone and they often visit very remote areas that are otherwise almost inaccessible and sightings of seabirds and marine mammals are among the highlights on these trips.

Tourism is increasing in importance in the Baffin Bay area and is one of the major sectors in the Greenland economy. Nature-based tourism in coastal regions is the primary component of this industry primary to the south of the license blocks. Cruise ships travel along the coast primarily in August and September.

5.15.2 Impact assessment

Tourism is primarily related to the coastal areas. As the license blocks are some 100 km from the shore, it is assessed that there will be no direct impact on tourism.

Table 5-31 Environmental impacts to tourism in connection with the 2013 site survey

Potential project impact	Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact	Level of confidence
-	-	-	-	No impact	High

5.16 Cumulative impacts

Different impacts may together result in a different impact than each one would separately, as certain impacts can reinforce or counteract other impacts.

As per January 2013, no other seismic surveys are announced in Baffin Bay, and no other surveys are announced in the license blocks. As such, no cumulative impacts are expected in relation to survey activities.

5.17 Transboundary impacts

Transboundary impacts relate to impact across borders, i.e. impacts to the Canadian part of Baffin Bay, and could be associated with maritime traffic or propagation of underwater sound. No transboundary impacts have been identified as part of the environmental impact assessment.

5.18 Summary of impacts

The results of the impact assessment are presented in Table 5-32, along with level of confidence. As is evident from the table, some impacts associated with the 2013 survey are moderate. Applying the identified mitigating measures, the residual impact is reduced to minor.

The main activity of concern is the underwater noise emitted by the seismic activities and this is summarized below. Routine activities associated with the site survey, e.g. discharges of grey water (showers, wash water) and black water (treated sewage) as well as the physical presence of vessels were assessed, as were the impacts of the benthic sampling planned for the environmental baseline survey (EBS). Impacts of routine activities and benthic sampling are not detailed in this summary because impacts were assessed to be minor.

5.18.1 Fish

At depths below app. 500 m, the Greenland halibut is the dominant species, while species like lumpfish, spotted wolffish, polar cod, capelin, greenland cod, atlantic cod, northern shrimp, snow crab and several species of sculpins, skates and rays also occur.

Noise from site survey has been assessed based on the modelled sound levels and criteria for behavioural and physiological response to underwater noise. Any physical impacts due to the exposure to single pulses are restricted to very close ranges from the source. Behavioural response in marine fish can occur at ranges just below 60 km. Impacts to fish associated with the seismic survey are assessed to be moderate.

5.18.2 Marine mammals

No resident populations are known to occur in the license blocks. Based on dedicated aerial surveys, the SEIA and MMSO data several species of marine mammals have been identified in this area. Key species of marine mammals assessed to potentially occur in the license blocks are bowhead whale, beluga whale, narwhal, bearded seal, ringed seal, walrus and polar bear.

Noise from site survey has been assessed based on the modelled sound levels and criteria for behavioural and physiological response to underwater noise. Overall, the only physiological effects that can occur with this type of sound source under the modelled propagation scenario are temporary threshold shift in bowhead whales close to the source. Behavioural response is expected in cetaceans (narwhals, beluga whales and bowhead whales) at ranges up to 6 km from the source, while seals are much less affected with behaviour potentially affected within 40 from the source.

The mitigation measures applied are 1) Marine mammals observers ensuring that no marine mammals are in the area prior to seismic start-up, 2) Soft start procedure gradually increasing the sound energy to provide time for mammals to leave the area, 3) Observations of the ‘safety zone’ (500 m) where survey is delayed if animals are observed, and 4) Passive Acoustic Monitoring (on board) in low visibility conditions. All four methods would effectively alleviate the risk of temporary threshold shift, and the residual impact is thus considered minor. Yet the behavioural impacts would not be mitigated as distances are larger and animals cannot be visually observed at these distances.

5.18.3 Protected areas

The license blocks are situated in a seismic protection zone for narwhal, appointed as a migration corridor (narwhal zone II). The protection zone is established to protect the fall migration habitat where the narwhals (and beluga whales) are present from 15 October at least until 1 Dec. Seismic activities in narwhal zone II shall be confined to a minimum in the protection period. As there is no overlap between the site survey and the protection period, it is assessed that there will be no impacts to protected areas.

Table 5-32 Summary of the overall severity of impacts, mitigating measures and residuel impact for parameters related to the planned 2013 site survey. The level of confidence for each impact assessment is also provided.

Parameter	Overall severity of impact*	Mitigating measures	Residual impact	Level of confidence
Climate and ice conditions	No impact	N/A	No impact	High
Oceanography	No impact	N/A	No impact	High
Bathymetry	No impact	N/A	No impact	High
Water and sediment quality	No impact	N/A	No impact	High
Plankton	No impact	N/A	No impact	High
Benthic fauna	Minor impact	No mitigating measures applicable	Minor impact	High
Fish	Moderate impact	No mitigating measures applicable	Moderate impact	Medium-High
Marine Mammals	Moderate impact	Marine mammal observers ensuring no marine mammals in the vicinity prior to seismic start-up Soft start procedure gradually increasing the sound energy to provide time for mammals to leave the area Observations of a safety zone (500 m) where the survey is delayed if animals are observed Passive acoustic monitoring system, enabling registration of marine mammals under adverse weather conditions.	Minor impact	Low-High
Protected areas	No impact	N/A	No impact	High
Seabirds	No impact	N/A	No impact	High
Commercial and recreational fishery	Minor impact	Spatial mitigating measures to reduce influence on fisheries are limited to changes of the order in which the survey locations are visited. This should be considered in dialogue with any fishing vessels operating in the area during the survey.	Minor impact	High
Maritime traffic	No impact	N/A	No impact	High
Tourism	No impact	N/A	No impact	High
Cumulative impacts	No impact	N/A	No impact	High
Transboundary impacts	No impact	N/A	No impact	High

Table 5-33 Criteria used in the environmental impact assessment for the planned 2013 site survey.

Intensity of impact	Scale of impact	Duration of impact	Overall severity of impact[1]
No	Local	Immediate	No impact
Minor	Regional	Short-term	Negligible impact
Medium	National	Medium-term	Minor impact
Large	Transboundary	Long-term	Moderate impact
			Significant impact

[1]: Evaluation of overall significance of impact includes an evaluation of the variables shown and an evaluation of the sensitivity of the resource/receptor that is assessed.

The environmental impact assessment is based on the best available information at this time. The license blocks are situated in Baffin Bay, ~100 km from land, in an area with limited data coverage. The main knowledge gap thus relates to site-specific data for the environmental parameter. Some studies have been carried out, but no structured repetitive surveys have been carried out in the license blocks.

6. IMPACT ASSESSMENT (UNPLANNED EVENTS)

The planned site survey consists of seismic activities and sampling. Unplanned events include and accidental spill and loss of equipment during sampling. Loss of equipment during sampling refers to e.g. loss of streamer, or loss of an anchor. As the lost equipment is expected to be comparable to the dropped steel weights in association with the moorings assessed in section 5, loss of equipment is not further addressed.

Preventative measures and plans will be in place to avoid any fuel spillage or other accidental events during the site survey, as described in section 7. Plans and measures include: spill prevention plans and ship-board oil pollution prevention plans, crew training, adherence to the safety management procedures including proper bunkering procedures, and drills. An ice management plan will be implemented and minimize the likelihood of vessel collisions with icebergs. In the unlikely event of a spill, impacts will be minimized; including use of appropriate onboard spill kits.

6.1 Spill scenarios

For the purpose of this EIA, two scenarios for accidental fuel spill (of marine gas oil) were assessed. The first assumes a small spill during routine bunkering of a vessel and the second assumes total fuel loss (marine gas oil) from a vessel following a vessel collision (with another vessel or an iceberg).

- Scenario 1 assumes a fuel hose rupture during bunkering from a supply vessel to the seismic vessel. Based on a fuel transfer rate of ~100 m^3/h and assuming it would take one minute for ship personnel to notice the leak and stop the fuel pumps, ~1.7 m^3 of fuel could be spilled overboard.
- Scenario 2 is a worst-case scenario spill considering total fuel loss of the vessel. As the vessel for the site survey has not been selected, the volume considered in relation to the 2012 survey if used, resulting in a worst case spill of 1,925 m^3. Such a spill is considered to be unlikely.

Refuelling of the survey vessel may, if necessary, occur in the license blocks, some 100 km from the Greenland coast, including the coastal areas identified as sensitive to spills in the SEIA /9/and oil spill sensitivity atlas for coastal areas of northwest Greenland /10/. Based on wind and current patterns described in the existing conditions (section 5) and the 2012 EIA /6/, an offshore fuel spill within the license blocks is more likely to move away from the coast, than towards the coast /6/.

6.2 Impacts to the marine environment

The recent strategic environmental impact assessment (SEIA) /9/ reviewed potential impacts of accidental oil spills (including larger scale subsurface blowouts during exploration drilling) and the following assessment refers to the SEIA for further details.

Water quality, and possibly **sediment quality**, would be susceptible to an accidental spill. As reviewed in the 2012 EIA /6/ marine gas oil is a light oil that persists in the environment for much shorter periods than e.g. crude oil or heavy fuel oils. In cold water, only about 50% of the spilled gas oil would remain on the water surface after 12 hours, and a spill of gas oil would thus not persist for long periods on the water surface. The remaining gas oil is split, with about half dispersed in the water column and the other half lost to evaporation. Based on the worst case scenario, the amount of marine gas oil that could be lost during a vessel collision (with another vessel or an iceberg) would form a diminishing surface slick for a few days to a week /6/.

The scale of a spill in a worst-case scenario is thus assessed to be regional with a short-term duration, and assessed to be minor.

Plankton (incl eggs and larvae of fish and invertebrates) are sensitive to hydrocarbon exposure. The occurrence, abundance and distribution of eggs and larvae of marine fish and invertebrate in the license blocks are likely to be highly variable by season and dependent on a variety of potential for individual invertebrate eggs and larvae in the upper water column to sustain lethal

and sublethal effects following contact with high concentrations of hydrocarbons. In relation to fisheries, larvae of Greenland halibut and shrimp are found in deeper waters and would be less likely to come in contact with a fuel spill at the water's surface. In the event of an accidental spill (which will be local and short-term), it is assessed that minor impacts to plankton may occur.

Under natural conditions, most juvenile and adult **fish** can actively avoid contaminated water /9/. Impacts to fish populations is considered minor, but with uncertainty related to lack of life cycle knowledge on most species.

Due to expected low densities of **marine mammals** in the license blocks, and the limited amounts of light fuel onboard the survey vessels, accidental discharges of marine gas oil are not expected to cause any impacts to seals or whales. Whales and seals rely on a layer of blubber, rather than fur, for insulation (except seal pups) and are generally not sensitive to a minor spill. As noted in the SEIA, the primary species in the license blocks that would be vulnerable to exposure to marine gas oil is the polar bear, which could have reduced insulation capabilities.

The primary effects of an accidental spill on **fisheries** relates to physical effects on target species and fouling of gear. As noted in section 5.13, little fishery is expected in the license blocks, primarily targeting Greenland halibut. Direct impacts to ongoing fishing activity will likely be aborting fishing to take part in SAR operations. As impacts on fish and marine invertebrates from a spill of marine gas oil are expected to be minor, it is assessed that impacts on fisheries will be minor. Further impacts to fisheries due to market perceptions of poor product quality (no buyers or reduced prices, etc.) are more difficult to predict, since the actual (physical) impacts of the spill might have little to do with these perceptions.

Seabirds are extremely vulnerable to fuel spills in the marine environment, as reviewed in /9/. Even a small amount of fuel may destroy the insulating and water-resistant properties and affecting the buoyancy of the plumage causing the bird to die from hypothermia, starvation or drowning. In addition, birds may get intoxicated from ingestion or inhalation of fuels when they are cleaning their plumages or are feeding on contaminated food. Intoxication may cause irritation of the digestive organs, damages to liver, kidneys and salt glands and leading to anaemia. The aggregative nature of many species of seabirds in Baffin Bay (especially little auks and Brünnich's Guillemots increases the potential for larger mortalities in case of an oil spill.

Transboundary impacts relate to impact across borders, i.e. impacts to the Canadian part of Baffin Bay. With the worst-case spill assessed to be regional with a short-term duration, no significant transboundary impacts are expected to occur.

7. ENVIRONMENTAL MANAGEMENT PLAN

An environmental management plan (EMP) has been prepared to address implementation and monitoring of agreed mitigating measures for the site survey. In effect, the EMP links the EIA to the execution of the site survey.

The EMP includes a description of the management structure and outlines the mitigating measures agreed for the site survey.

7.1 Management structure

Shell is the operator for the license blocks and is managing the site survey activities.
The site surveys will be undertaken by a specialist contractor, who will be responsible for the day-to-day operation of the vessel and the site survey programme. A client representative will be stationed on board the vessel and will be responsible for ensuring compliance with contract scope and specifications, audit of data quality, monitoring implementation of project HSSE plan and monitoring project progress.

7.2 Planning phase

An Environmental Impact Assessment (EIA) must be prepared, describing the environmental conditions and assessing potential impacts. As part of the EIA seasonal considerations (e.g. pupping, migration of marine mammals) are addressed.

Airgun array must be chosen to use the lowest practicable power levels to achieve the geophysical objectives of the survey. The airgun array for the 2013 survey has yet to be selected, and the EIA includes acoustic modelling based on conservative assumptions. The assumptions are based on parameters from previous surveys, literature and experience.

The Seismic EIA Guidelines request operators to seek methods to reduce and/or baffle unnecessary high-frequency noise and to increase the directionality of the airguns. These potential mitigation measures have been assessed in a Joint Industry Programme study /87/. It was determined that the equipment necessary to reduce and/or baffle the airguns is not yet available.

Communication with the relevant stakeholders (e.g. authorities, other operators and local interest groups) will be established as a minimum according to regulatory requirements. In addition to informing about the project, such communication allows the operator to assess cumulative impacts, e.g. if seismic surveys are planned in neighbouring license blocks.

7.3 Survey phase

7.3.1 Marine mammals – seismic mitigating measures

As evidenced in this EIA, the main impact is that of airgun array noise on marine mammals. This EMP focuses on minimizing noise impacts and is based primarily on the best practice mitigation guidelines described in the BMP Guidelines /3/.

Marine mammal (and seabird; see below) **observations** will be performed from the survey vessels allowing an unobstructed view of the waters around the vessel. Whenever possible, the MMSOs will conduct observations from an outdoor platform. During periods of poor weather (high winds, rain/snow, or extreme cold temperatures), the MMSOs will continue monitoring for marine mammals and seabirds from the bridge for safety reasons. MMSOs aboard each of the seismic vessels will monitor for the presence of marine mammals (and seabirds) during all daylight hours. At all times, MMSOs will have access to a direct communication line with the survey room and the operator of the airguns. A safety zone of 500 m from the centre of the airgun array will be implemented for marine mammals, based on international best practice.

Table 7-1 summarizes the operational monitoring and mitigation measures proposed for Shell's seismic program. Flow-charts will be developed that clearly outline the decision-making process for implementing mitigation and monitoring procedures.

During periods of poor visibility (when the 500-m safety zone for marine mammals, respectively cannot be monitored because of darkness or poor sighting conditions such as fog, rain, snow, or sea states >3), **PAM** will be used during the pre-shooting watch period to monitor for vocalizing marine mammals within the safety zone. The safety zone monitored by the PAM system will be determined in the field to ensure it extends beyond 500 m to compensate for the system's accuracy. If any marine mammal is visually or acoustically detected within the safety zone during the pre-shooting watch period, the ramp-up will be delayed until the animal has been observed outside of the safety zone or 20 min has passed since the animal was last detected.

A **pre-shooting search** of 30 min (60 min in water depths of >200 m) will be conducted before the start of any airgun operations.

If the airgun array is shut down while on a transect line for any reason other than a marine mammal **shutdown**, the airgun array can be re-initiated at full power given that the shutdown is not longer than 5 min. Otherwise, a 20-min search and full ramp-up procedure will need to be initiated. When a marine mammal is observed to be on a course that will result in its entering the safety zone, a precautionary shutdown of the airgun array will be implemented.

The ramp-up or **soft start procedure** will occur over a minimum period of ~20 min. Ramp up will start with the smallest volume airgun and incrementally increase the number of airguns activated. The procedure will be planned such that the start of the survey line begins immediately following the ramp up (i.e., unnecessary airgun firing will be avoided). Ramp ups will not exceed 40 min in duration, and to the extent possible will be initiated during daylight hours. During periods of poor monitoring visibility (when the 500-m safety zone for marine mammals cannot be monitored because of darkness or poor sighting conditions such as fog, rain, snow, or sea states >3), PAM will be used during the ramp-up procedure to monitor vocalizing marine mammals within the safety zone. If any marine mammal is visually or acoustically detected within the safety zone during the ramp-up procedure, the airgun array will be reduced to the mitigation gun (smallest airgun in the array) and a new ramp-up procedure will be initiated once the animal has been detected outside of the safety zone or 20 min has passed since the animal was last detected.

When the airgun array is **shut down**, either because of marine mammals within the safety zone or for other reasons, the mitigation gun will continue to be used. If a marine mammal is observed within the 500-m safety zone for marine mammals, the airgun array will be reduced to the mitigation gun until the animal has left the safety zone. When this situation occurs, the airgun array can return to shooting at full power without requiring a ramp-up procedure in cases where (i) the animal is observed to have left the safety zone and (ii) the maximum time of the silent break (period between shut down and start up) is 5 min. If this period is longer than 5 min or the animal is not observed leaving the 500-m safety zone for marine mammals, a 20-min pre-shooting search period followed by a 20-min ramp-up procedure will be used before line shooting can resume.

Line Changes. The airgun array output will be shut down when the transit time to the next survey line is expected to be greater than 20 min (the amount of time it would take to conduct a full ramp-up procedure). A 30 min (60 min in water depths of >200 m) pre-shooting search and full ramp-up procedure will be initiated before the start of the next survey line.

If a transit between survey lines is expected to last less than 20 min, the airgun array can remain operational during transit, but preferably at a reduced power output (mitigation gun). No ramp-up procedure will be required at the start of the next survey line.

Table 7-1 outlines the measures that will be taken to avoid or mitigate environmental impacts. All crew members, including support crew, will be made aware of the standards and controls applicable to the conduct of this survey before surveying commences.

Table 7-1 Summary of operational monitoring and mitigation measures for Shell's 2013 site survey

Marine mammal and seabird observers (MMSOs)
• MMSO observations will be performed from the survey vessels on an elevated platform allowing an unobstructed view of the waters around the vessel. Whenever possible, the MMSOs will conduct observations from an outdoor platform.
• MMSOs aboard the seismic vessel will monitor for the presence of marine mammals during all daylight hours and via on board PAMs in low visibility conditions.
• MMSOs will have access to a direct communication line with the operator of the airguns.
• A safety/shut-down zone of 500 m for marine mammals will be implemented and monitored for the presence of marine mammals during all daylight hours.
Passive acoustic monitoring (PAM)
• During periods of poor visibility, the on board PAM system will be used during the pre-shooting watch period to monitor for vocalizing marine mammals within the safety zone. PAM will also be used at night and during fog.
• If any marine mammal is visually or acoustically detected within the safety zone during the pre-shooting watch period, the ramp-up will be delayed until the animal has been observed outside of the safety zone or 20 min has passed since the animal was last detected.
• PAM will also be used to shut down during acquisition.
Pre-shooting search
• A pre-shooting search of 30 min (60 min in water depths of >200 m) will be conducted before the start of any airgun operations.
Shutdown
• If any marine mammal is observed within the 500-m safety zone for cetaceans (and walruses) and other marine mammals, respectively, the airgun array will be reduced to the mitigation gun.
• A precautionary shutdown will be applied if a marine mammal is observed to be on a course that will result in its entering the shutdown zone.
Soft start
• The soft start procedure will occur over a minimum period of ~20 min. Soft start will not exceed 40 min in duration and to the extent possible will be initiated during • daylight hours.
• The ramp-up procedure will be planned such that the start of the survey line begins immediately following the ramp-up.
• Soft starts will to the extent possible will be initiated during daylight hours.
• During periods of poor monitoring visibility, the onboard PAM system will be used during the ramp-up procedure to monitor vocalizing marine mammals within the safety zone.
• If any marine mammal is detected within the safety zone during the soft start, the airgun array will be reduced to the mitigation gun and a new ramp-up procedure will be initiated once the animal has been detected outside of the safety zone or 20 min has passed since the animal was last detected.
• If any marine mammal is detected within the safety zone while on the transect line, the airgun array will be reduced to the mitigation gun and a new ramp-up procedure will be initiated if the silent break (period between shut-down and start-up) exceeds 5 minutes or 20 min has passed since the animal was last detected. If the animal is observed outside the safety zone within 5 minutes after shut-down, the airgun array can be started at full power without ramp-up.
• If the airgun array is shut down for any reason other than marine mammals while on the transect line, the airgun array can be re-initiated at full power given that the silent break is not longer than 5 min. Otherwise, a 20-min pre-shooting search and full ramp-up procedure will need to be initiated.

Line changes
• The airgun array output will be shutdown when the transit time to the next survey line is expected to be greater than 20 min.
• A 30 min (60 min in water depths of >200 m) pre-shooting search and full ramp-up procedure will be initiated prior to the start of the next survey line.
• If a transit between survey lines is expected to last less than 20 min, the airgun array can remain operational during transit, but preferably at a reduced power output (mitigation gun). No ramp-up procedure will be required at the start of the next survey line.

7.3.2 Seabirds

Systematic seabird surveys will be conducted to the maximum extent possible and by experienced seabird observers (MMSOs). Seabird observations will be undertaken using the follow the protocol outlined in the Manual for seabird and marine mammal survey on seismic vessels in Greenland on vessels that include MMSOs.

Deck lighting will be minimized (especially upward and horizontal-projecting light) to the extent that it is safe and practical to reduce the likelihood of birds stranding on Project vessels. Daily searches of Project vessels will be conducted for stranded birds. Project personnel will be made aware of bird attraction to the lights on offshore structures. However, some degree of lighting is required for safe work practices, and seismic surveying is conducted around the clock. The MMSOs will conduct daily searches of the ship, and the ship's crew will also be notified to contact the MMSOs if a bird is found.

7.3.3 Fisheries Interactions

The BMP Guidelines state that the licensee shall, upon BMP request, include one or more Fishery Liaison Officers (FLO) in the operation. If a FLO is required, a logbook of observations will be kept. It is not anticipated that a FLO will be required considering the location of the license blocks.

Vessel crews will keep a log of sightings and contacts with fishing (and other) vessels. In addition, a log will be kept of any unused fishing or other equipment removed from the sea for the purpose of clearing a path for the survey vessels. The log will include location, date, type of equipment, and any identifying marks.

No hunting or fishing will be permitted from Project vessels or from in-going or out-going individuals while on land during crew change operations.

7.3.4 General Ship Operations

Project vessels will operate in accordance with all applicable laws, standards and conditions while in Greenland waters.

The impacts of vessel traffic on marine mammals will be reduced by vessels steering a straight course and maintaining constant and moderate speed (less than 14 knots) whenever possible. Shell is committed to these mitigation measures to the extent that is possible and practical for their operations. Maintaining a constant and moderate speed will reduce changes in sound levels and frequencies of engine and propeller sounds that disturb marine animals.

7.3.5 Other Environmental Conditions

The BMP's Application Guidelines /2/ also note requirements related to other environmental conditions and considerations:

- When acquiring seismic data, the operation shall be conducted in accordance with the Best Practices listed in the BMP guidelines
- All non-degradable materials and structures shall be removed upon termination of the operation, unless BMP approves otherwise.
- Discharge of wastewater and kitchen waste shall be in compliance with the provisions of Annex IV and Annex V of the MARPOL Convention.
- Hunting and fishing is not permitted in connection with exploration activities, unless specific permission is given by the Greenland Government. [Note that hunting and fishing from Project vessels will not be permitted by Shell.]
- BMP may, when approving specific exploration activities, require the licensee to perform further impact studies and/or limit the operation to certain periods or from certain areas.
- Vessels engaged and machinery used in the exploration activities shall only use marine gasoil with a sulphur content less than 1.5 % (weight). Heavy fuel oil and oil with a sulphur content >1.5 % must not be used.

Shell will comply with each of these requirements (as described above) and will brief Project personnel about these and all other environmental commitments and requirements during in-person start up meetings before survey start (expected July 2013).

7.3.6 Reporting

Marine mammal and seabird observation databases, along with a monitoring report, will be submitted to BMP and DCE within two months of completion of the seismic program.

If a fisheries liaison officer is requested onboard, a logbook of observations will also be reported to BMP.

7.4 Communications

Engagement with local communities will take place before, during, and after the seismic operations to ensure that community concerns are heard and acted upon wherever possible. Other aspects of Shell's communication approach are provided below.

- Shell staff will be present in Greenland to maintain close relationships with stakeholders and to respond to potential issues.
- A grievance mechanism will be established, offering various ways (e.g., telephone, email, personal contact) to enable local stakeholders to contact Shell directly to ensure timely resolution of concerns and complaints.
- Shell will continue to communicate with other operators during the planning and operation phases to avoid interactions and minimize impacts.
- Shell will contact the DCE prior to survey start to ensure that its monitoring and mitigation plan for marine mammals and seabirds meets DCE protocols.
- Shell will be available to meet with local stakeholders after the proposed survey program to present the findings of the marine mammal and seabird monitoring program.
- To make sure that all survey personnel are aware of the environmental issues and mitigation measures that will be applied for the 2013 survey, Shell environmental and Project management personnel will hold a meeting with the survey vessel crews and managers before the start of the program to ensure full compliance.

7.5 Unplanned Events

As part of Shell's application for permission, Shell will submit to BMP a description of the safety management system and bridging documents for the health, safety, security, and environmental management systems in a separate document to this EIA, no later than 40 days prior to the anticipated survey start. These documents will include roles and responsibilities of all parties in the event of an emergency or accident during the 2013 program, including an Emergency Response Plan, Spill Response Plan that will include bunkering procedures to be used, and an Ice Management Plan. The following measures will also reduce the likelihood of an unplanned event.

- Vessel contractors will be made aware of relevant national legislation and guidelines, as well as follow International Maritime Organization best practices and guidelines such as *Guidelines for Ship Operating in Polar Waters*.
- Drills are a regulatory requirement and are carried out at regular intervals during which the oil spill response kit is checked. These oil spill drills encompass bunkering in port and at sea and machinery leaks, and form a part of the emergency onboard drills matrix.

BMP and Shell shall be notified immediately of any significant accidental event, including loss of life, missing persons, serious injury, fire, oil spill, and any threat to the personnel or the safety of the survey vessel. Any spills or unplanned releases will also be recorded and reported to appropriate authorities.

APPENDIX 1
INTRODUCTION TO UNDERWATER SOUND

For a better understanding of the technical terms used in this report, this Appendix will provide a short introduction into underwater sound.

Sound in water is a travelling wave in which particles of the medium are alternately forced together and then apart. The sound can be measured as a change in pressure within the medium, which acts in all directions, described as the sound pressure. The unit for pressure is Pascal (Newton per square metre). Each sound wave has a pressure component (in Pascals) and a particle motion component indicating the displacement (metres), the velocity (metres per second) and the acceleration (metres per second^2) of the molecules in the sound wave. Depending on their receptor mechanisms, marine life is sensitive to either pressure or particle motion or both. The pressure can be measured with a pressure sensitive device such as a hydrophone (an underwater microphone).
Due to the wide range of pressures and intensities and taking the hearing of marine life into account, it is customary to describe these using a logarithmic scale. The most generally used logarithmic scale for describing sound is the decibel scale (dB).

The sound pressure level (SPL) of a sound is given in decibels (dB) by equation 1:

$$SPL \text{ (in dB)} = 20 \log_{10} (P/P_0)$$

where P is the measured pressure level and P_0 is the reference pressure. The reference pressure in underwater acoustics is defined as 1 micropascal (µPa). As the dB value is given on a logarithmic scale, doubling the pressure of a sound leads to a 6 dB increase in sound pressure level. As the reference pressure for measurements in air is 20 µPa, and water and air differ acoustically, the dB levels for sound in water and in air cannot be compared directly.

Most animals, including marine mammals, are sensitive to sound pressure. On the other hand fish and many invertebrates are also sensitive to the local particle motion of the sound field.

Measurements of Sound
A sound wave can be analysed and measured in several different ways. Figure 1 illustrates the different measurement units.

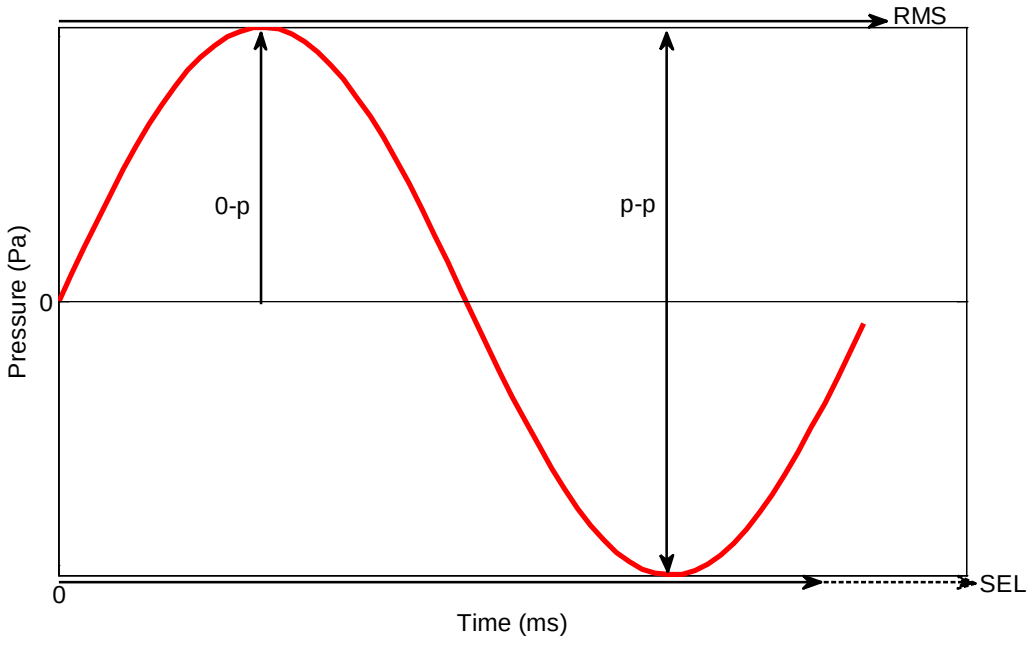

Figure A1-1 Waveform of a sine-wave with indications of the different measurement units.

The four different measurement units depicted in Figure 1 are:

- Zero-to-peak' (peak) – dB p; the interval from zero to the maximum amplitude of the signal.
- 'Peak-to-peak' (peak-to peak) – dB p-p; the interval from the lowest to the highest amplitude of the signal.
- 'Root-mean-square-pressure level (RMS) – dB rms; the square root of the average squared signal pressure divided by the duration of the signal. This term is synonymous for sound pressure level.
- 'Sound-exposure-level (SEL) – dB AE/dB SEL; the total energy content of the signal, measured by integrating the squared signal pressures over time.

All these measures are made on the pressure waveform of the signal. The re-calculation into decibels transforms the values into relative measures of intensity or energy.

For a simple sine-wave with signal duration ~ 100 ms, peak-to-peak levels will be the highest, followed by zero-to-peak, RMS, and finally SEL. However, if the duration is longer than 1 s, the SEL-level will be higher than the RMS level.

Peak and peak-to-peak sound pressure values refer to the amplitude of a given sound and are therefore not dependent on the choice of time window as are the RMS and SEL measures. They are suited for the description of short impulsive sounds such as airguns. In hearing studies the stimulus is often a pure tone measured with RMS, and therefore thresholds are often given in sound pressure levels. When calculating detection distances it is therefore easiest to use the sound pressure level of the signal to compare with the audiogram.

SEL-values are calculated by measuring the sound energy of a signal with reference to a 1 µPa RMS signal of duration 1 s (see above). SEL is given in the unit dB re 1 $\mu Pa^2 s$.

For transient sounds it is not sufficient to only report an RMS level, as both the peak and the RMS level is important when assessing the effects on animals. Further, the choice of time window for calculating the average is strongly affecting the resulting RMS level (Madsen 2005). Therefore, the choice of time window should always be reported. However, the RMS is often the only measurement available in many reports. In the following, the presented values are given in RMS units with unknown choice of time window.

APPENDIX 2
ACOUSTIC MODELLING

1. EXECUTIVE SUMMARY

2D seismic surveys are to take place at up to ten locations in Baffin Bay (West Greenland) in the summer of 2013. The surveys will be restricted to areas (3x3 km) around proposed drilling sites and will occur at depths of 500 – 800 m. 2 D seismic surveys go along with sound pressure levels that have the potential to impact marine life (marine mammals and fish) at the site and in adjacent areas. We present the results of an acoustic propagation modelling study of the expected noise exposure from the planned 2D seismic surveys to be included in the supplied EIA. The model is based on actual bathymetry information covering the entire area and basic knowledge of sediment properties. We also used detailed data on the vertical sound speed profiles during the time of the proposed survey (July – October). Horizontally, our model intends to cover all areas exposed to levels likely to affect marine mammals. Different from previous investigations, we also include frequencies above 2 kHz in the modelling to better match the acoustic sensitivity of some of the marine life in the area.

Based on information about the airgun array that will be used and literature data we used a zero to peak source sound pressure level of 230 dB re 1 µPa as the input variable in this study. The resulting peak to peak source sound pressure level was defined as 236 dB re 1 µPa. For the frequency spectrum we used a modelled far-field signature and the corresponding frequency spectrum of a representative array and scaled it to meet the source strength identified for this study. Based on the derived spectrum, the resulting broadband SEL level was 214 dB re µPa^2·s. RMS values were directly derived from SEL values and resulted in a source sound pressure level of 227 dB re 1 µPa. The calculation of the sound levels at different distances from the sources was undertaken for frequencies up to 4 kHz using a 2D numerical model of the underwater acoustic propagation. For this we used the well-established AcTUP package. We applied the RAMGEO code which is a full Parabolic Equation model.

For the quantitative assessment of impact ranges, we have chosen several criteria for marine mammals and fish derived from a variety of sources. The used NMFS criteria are part of the US regulation. Applicable are also the initial scientific recommendations on marine mammal noise exposure criteria as developed by a group of US experts. Recent work on fish has resulted in evidence based criteria for this taxa that we have applied directly.

The results of the modelling show a sharp decrease of sound levels in the first km from the source and a smoother decline in sound pressure levels at a longer range. Higher frequencies than 1 kHz where attenuated more rapidly than those below 1 kHz although not as drastically as expected. Furthermore, the difference in propagation loss across sites was very small indicating that results obtained here can be transferred somewhat to other sites if the development is relocated.

For the 2D high resolution surveys TTS will be limited to areas close to the source (80 m in cetaceans and 40 m in for pinnipeds). The onset of behavioural response can be expected in all three cetacean species at distances of approx. 6 km from the source with little difference between the sites. For seals, behavioural responses are only expected at close ranges (40 m).

For fish, the onset of any behavioural reactions can take place at a maximum distance of 59 km.

Looking at the cumulative sound fields (sound over a 24 h period including the survey), it is clear that impact ranges can be larger than for single shots. Yet, the assumption that the acoustic energy just sums up at the receiver in the way suggested by the calculations, neglects that hearing might recover between pulses. Thus, the overall impact from the survey over the course of a one-day cycle might be smaller than indicated in the cumulative maps.

2. INTRODUCTION

2D seismic surveys are to take place at up to ten locations in Baffin Bay (West Greenland) in the summer of 2013. The surveys will be restricted to areas (3x3 km) around proposed sites and will occur at depths of 500 – 800 m. The surveys will be restricted to areas (3x3 km) around the proposed drilling sites. 2D seismic surveys go along with sound pressure levels that have the potential to harm marine life (i.e. marine mammals and fish) at the site and in adjacent areas (for a review of seismic survey impacts refer to OSPAR, 2009). According to the BMP guidelines (see Kyhn et al., 2011), the areas where sound might impact marine life shall be modelled. This should include an estimate of the source levels included in the model and the numerical modelling of the propagation loss from source to a distance out where impacts are negligible. The modelling will make use of internationally accepted units (peak SPL, SEL etc.). The results of the modelling shall be included in the impact assessment on marine mammals and fish.

2.1 Aims

Here we present a model of the expected noise exposure from 3 locations areas located in the prospect areas for drilling in Baffin Bay to be included in the supplied EIA. The model is based on actual bathymetry information covering the entire area and basic knowledge of sediment properties. We also used detailed data on the vertical sound speed profiles during the time of the proposed survey (July – October). Horizontally, our model intends to cover all areas exposed to levels likely to affect marine mammals (see noise exposure criteria in the EIA report and Southall et al. 2007).

The seismic noise propagation model will result in sound levels at different ranges and depths from the airgun array (depths relevant for the species in the area). Noise levels presented in the model are:

- zero-to-peak sound pressure levels referenced to 1 µPa (zero-peak),
- Peak-to-peak sound pressure levels referenced to 1 µPa (peak-peak),
- rms sound pressure levels referenced to 1 µPa (rms measured over 90% of pulse duration, as defined by Madsen, 2005; in the following this will be referred to the sound pressure level following the terminology suggested by TNO, 2011)
- Sound exposure levels (SEL[1]) referenced to 1 $\mu Pa^2 \cdot s$ per pulse.

For the assessment of cumulative effects also the cumulated sound exposure level (across all airgun pulses) per 24 hours is being presented.

Modelling will cover all biologically relevant parts of the frequency spectrum as much as these frequencies carry any substantial distance out from the source.

3. METHODS

3.1 Model areas and environmental conditions

The modelling of the 2D surveys shall be performed at three locations in Baffin Bay shown in Table A2-1 and in Figure A2-1. These locations were the initially proposed survey sites but can be viewed as representative for similar conditions (nearby location and similar water depth) in the licensing blocks.

[1] The sound exposure level (SEL) is often used in the assessment of noise impact on the sea environment and is a measure of the total energy of the noise normalised to 1 second.

Table A2-1 Overview of the three survey locations (E = Easting; N = Northing).

Location Designation	Coordinates (WGS84/UTM21N)
Location 1	E: 370700, N: 8274502
Location 2	E: 360764, N: 8248717
Location 3	E: 343898, N: 8181657

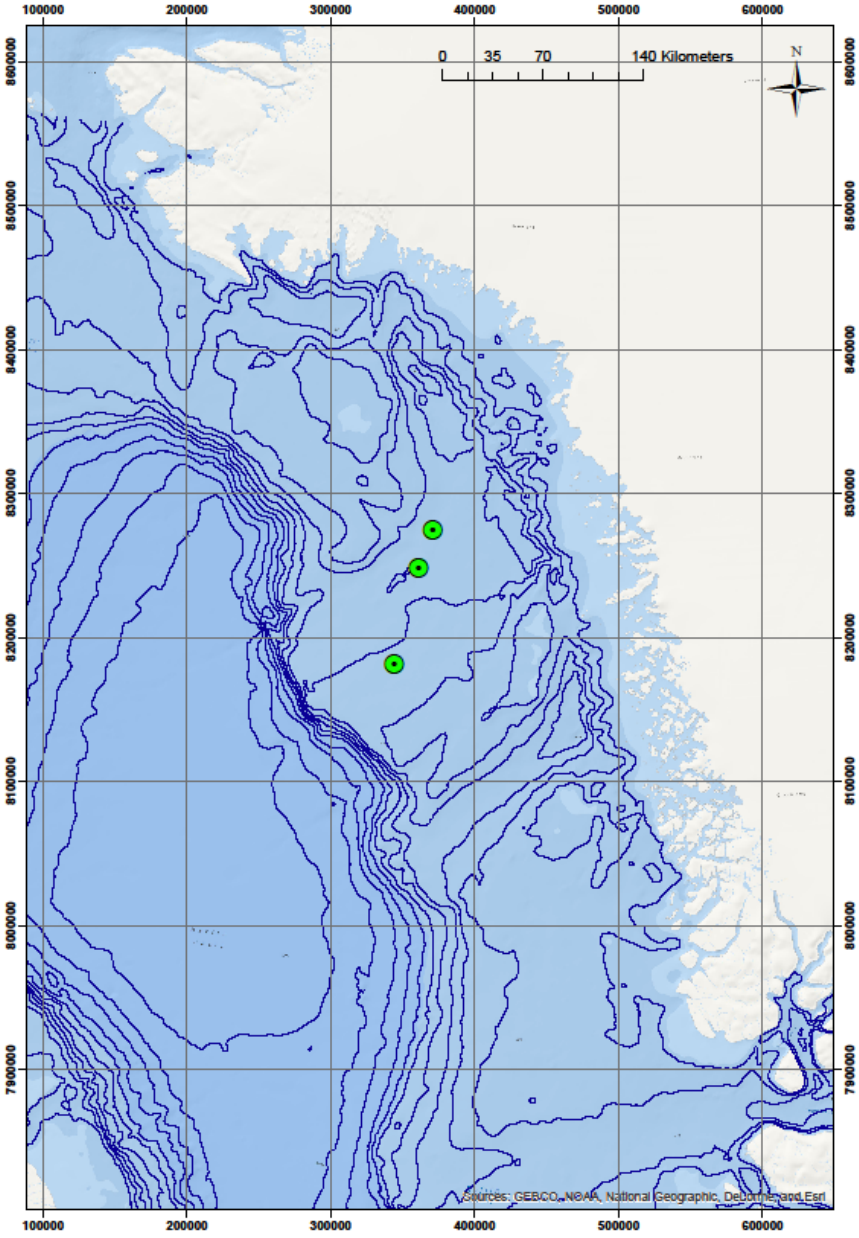

Figure A2-1 Overview of the three locations for which the modelling of the 2D seismic surveys was undertaken (green circles are chosen for better visibility only).

Based on previous investigations and literature data on the assumed sound spread (see for example OSPAR, 2009), it was assumed that the modelling area should at least include areas 150 km away from the source in all directions. We thus chose 10 azimuth traces with a length of 150 km each (depending on coastal barriers). An example of the **bathymetric** profile around one location is shown in Figure A2-2 (see also chapter 7.1). It is clear from the plots that study area (= survey area and 150 km radius around each source) is diverse and covers marine landscapes of several hundred to app. 2,500 metres of water depths.

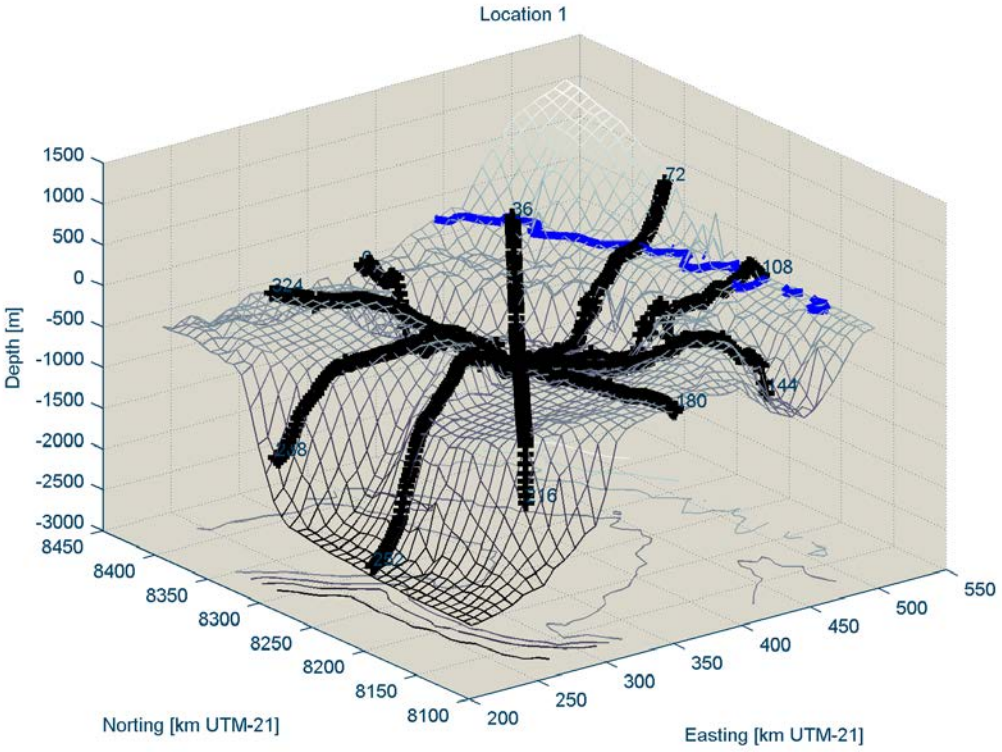

Figure A2-2 3-D bathymetric profile of source location 1 (source SRTM-30 geographic grid interpolated onto a 1 km x 1 km grid in UTM-21 coordinates; note that resolution mesh in the figures does not correspond to the actual resolution, but is only shown for reference; blue line = shore line; length of each trace is 150 km)

With regards to the **sound speed profile,** measurements undertaken by Shell in Baffin Bay Blocks 5 – 8 clearly show a rather uniform profile during that time of the year (Figure A2-3). We therefore took the average of each measurement at defined water depth intervals to arrive at an idealized plot for the survey time. Water depth > 700 m were extrapolated from the measurements.

The lowest sound speed in the water column is observed at depth ~70 m. Since sound rays bent towards regions of lower sound speed, the minimum in the profile acts as an acoustic waveguide, known as the Deep Sound Channel, in which energy from a source near the minimum may be trapped, allowing it to propagate with little loss to very large ranges; as much as several thousand kilometres. The axis of the deep sound channel is between the deep isothermal region and the mixed layer of almost constant temperature due to wind and wave activity.

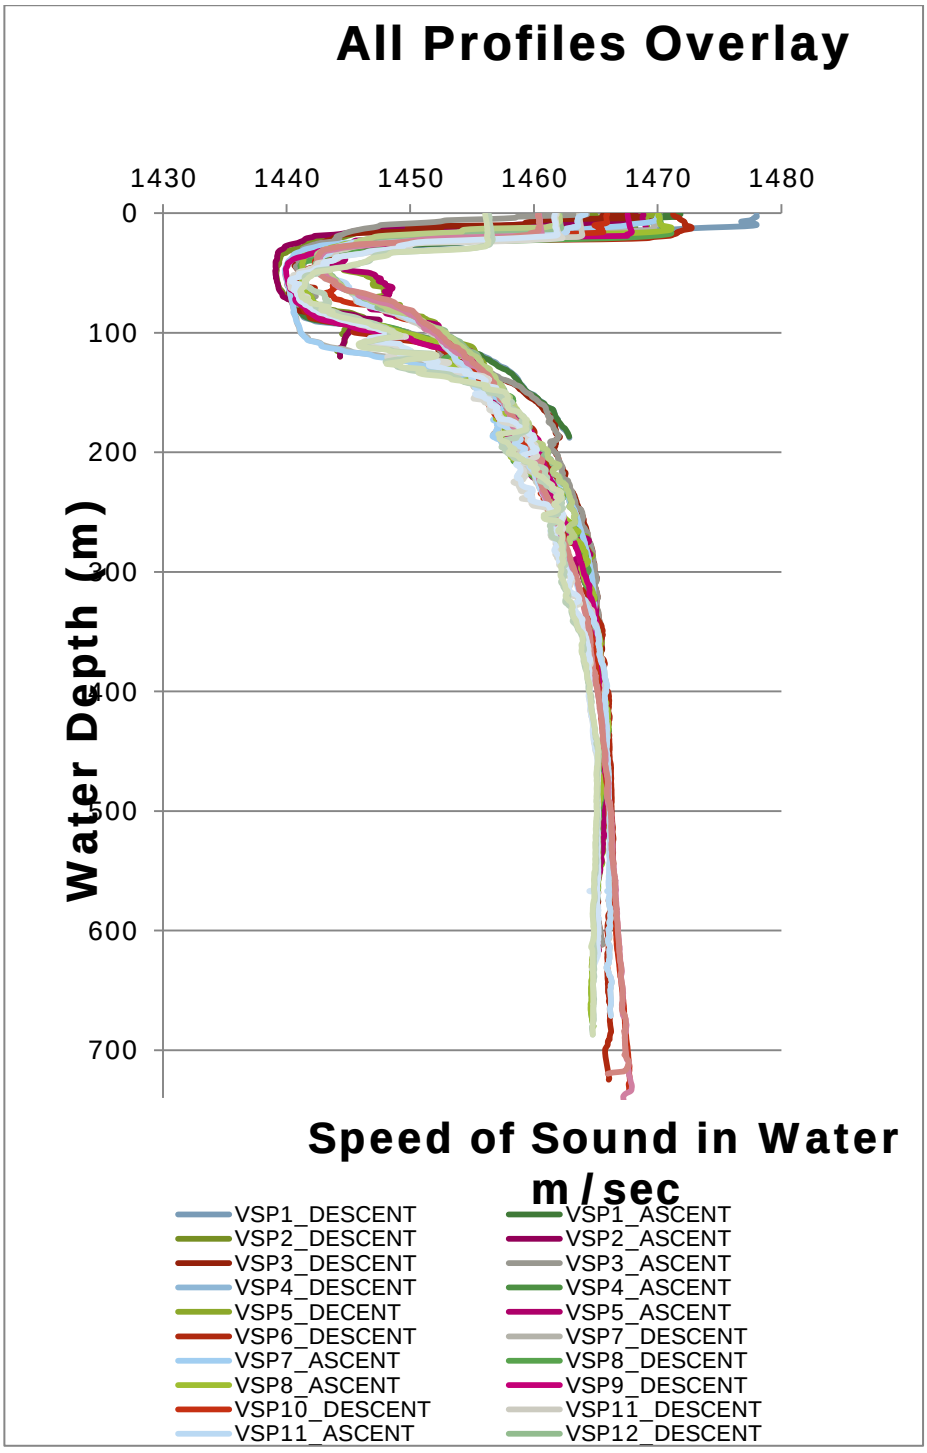

Figure A2-3 Measured sound speed profiles in Baffin Bay Blocks 5 – 8 during July - October 2012

The **geoacoustic data** was derived from Henriksen et al., 2000 from a representative cross-section of Baffin as well as from data gathered by Codispoti et al., 1968. The layers used in the modelling and the main parameters are depicted in Table A2-2.

Table A2-2 Overview of seabed geoacoustic profile used for the modelling (C_p = compressed wave speed, α = compressional attenuation, p = density).

Seabed layer (m)	Material	Geoacoustic property
0 – 20	Mud and clay	C_p = 1600 m/s α = 0.2 dB/λ P = 1.80 g/cm^3
20 – 160	Glacial deposits and coarse sediments	C_p = 1700 m/s α = 1.05 dB/λ P = 1.80 g/cm^3
➢ **160**	Glacial deposits and coarse sediments	C_p = 2000 m/s α = 0.85 dB/λ P = 2.05 g/cm^3

3.2 Survey parameters

The proposed activities for 2013 involve 2D high resolution seismic survey. In a 2D seismic survey, the vessel follows lines or a grid where the lines are a certain distance apart. One sound source is used, which is composed of several airguns to form an air gun array, and one hydrophone cable.

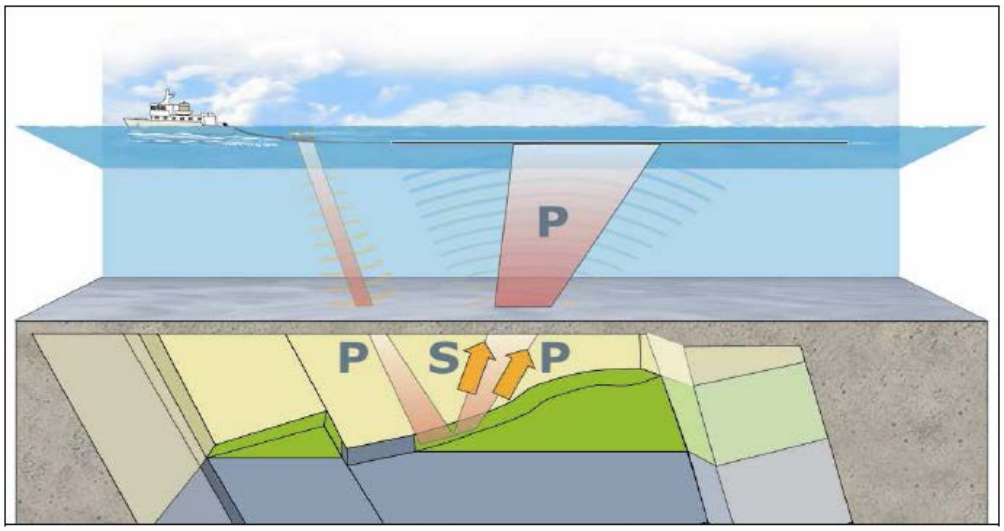

Figure A2-4 Schematic diagram for a 2D seismic survey. The vessel tows a sound source and a receiver cable with hydrophones. P=pressure waves. S=shear waves. (DNV 2007)

The following more detailed information on the survey design was acquired from the client.

Table A2-3 Main parameters of the 2 D survey

Survey information	Parameter
Type of survey (2D etc.)	2DHR
Start and end dates of each survey	Earliest start 15/7/2013; survey period is July – October 2013
Expected duration	Max 4 Weeks on site
Duty cycle of operation (in hours/24 hours)	24 Hours
Survey outline	Survey lines are 100 m apart (cross lines every 250 m)
Array specification	4x40" sleeve gun array
Array positioning	Source Depth 2.5m; Streamer Depth 2.5m
Firing rate in shots/sec	Shot point interval 6.25 m at 4 knots (1 shot per 3.125 s) 0.32 shot/sec (total ~13 h)
Operation speed of the vessel in km/hours or knots.	4 kn

3.3 Noise modelling

Air-gun arrays are designed to produce a single downward-directed impulse that propagates through the water column and into the seabed. Unavoidably, some sound energy also radiates horizontally from the array creating a complex radiation pattern. The presence of multiple propagation paths involving surface and bottom bounces as well as the re-radiation of sound reverberating within sub bottom layers increases the complexity of the received signal and can give rise to long reverberant wave forms of several seconds at long ranges.

3.3.1 Source information

The 2D survey that has to be assessed here is a site survey used to investigate the proposed locations for drilling. The surveys are similar to conventional 2D seismic surveys, except that the source used is comprised of a smaller volume of compressed air such as in this case with the overall 160 cubic inches involving only four airguns. Since the source is relatively simple, the directivity of the array was taken to be omni-directional providing the same noise radiation in all azimuth angles. This is a conservative approach as it will most likely lead to overestimation of the noise field in some cases.

Looking at the source strength, Genesis, 2011 and Wyatt, 2008, provide a comprehensive review of a variety of airguns and airgun arrays. According to their analysis, the emitted sound field is a function mainly of the size and the number of airguns and the overall emitted psi values (see Figure A2-5).

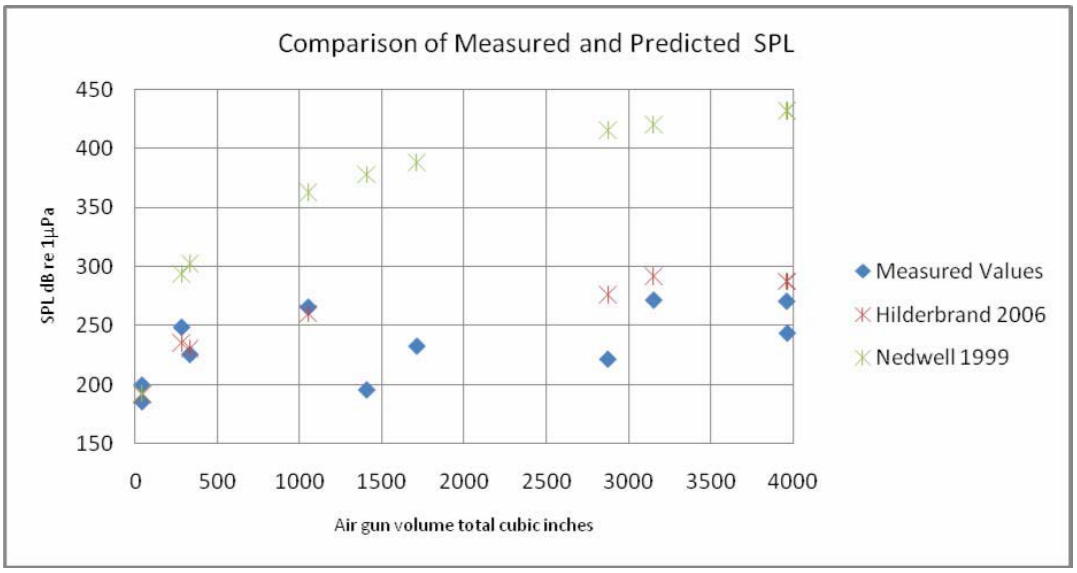

Figure A2-5 Comparison of measured and calculated air gun SPL in relation to airgun volume (from Wyatt, 2008).

As can be seen in Figure A2-5, the SPL below 500 cubic inches lie somewhere between 200 and 250 dB re 1 µPa. According to Ainslie, 2010, the zero to peak dipole source level of a 0.7 L 40 in^3 small gun was 224 dB re 1µPa at 1 m^2. A medium gun (2.5 – 1.0 L and 150 – 250 in^3) had a zero to peak dipole source level of 229 – 230 dB re 1 µPa. The latter represents the proposed volume for the Baffin Bay survey and as a conservative measure the higher zero to peak value of 230 dB re 1 µPa should be used in this study. The differences between the zero to peak values and the peak to peak values were set at 6 dB resulting in a peak-to-peak source sound pressure level of 236 dB re 1 µPa for the array (see Genesis, 2011).

For the frequency spectrum we used a modelled far-field signature and the corresponding frequency spectrum for frequencies up to 1 kHz of a representative array (see DHI, 2011) and scaled it to meet the source strength identified for this study. We decided to include frequencies of up to 4 kHz as it has been shown that they can, in some circumstances contribute to the noise levels and considerable distances, and also because the marine mammals subject to the assessment are sensitive in this frequency range (see Madsen et al., 2006). For frequencies above 1 kHz, the source spectrum was extrapolated assuming a 18 dB / octave slope (see, for example Wyatt, 2008). The resulting spectrum is shown in Figure A2-6.

[2] The sound source level is defined as the effective level of sound at a nominal distance of 1 meter. dB re. µPa. at 1 m.

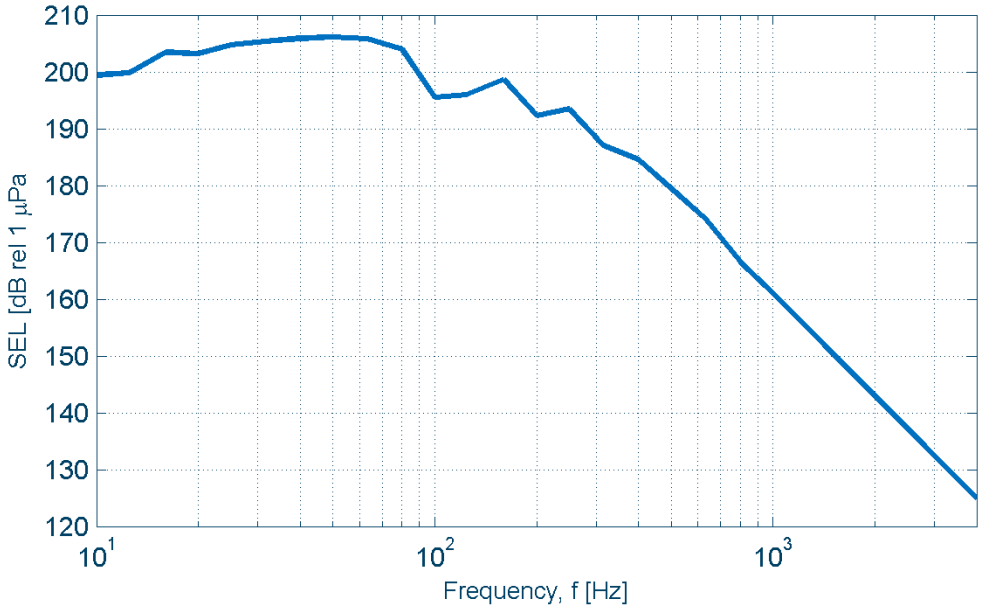

Figure A2-6 1/3 Octave frequency spectrum of seismic survey array far field signature.

Based on the derived spectrum, the resulting broadband SEL level was 214 dB re µPa^2·s. This corresponds well with measurements. Genesis, 2011 lists zero-to-peak and SEL values for a variety of airguns and airgun arrays, and based on their review it can be seen that on average the SEL values are about 20 dB below the zero-to-peak values. RMS values can then be derived from SEL values following

$$SPL_{rms} = SEL + 10\log_{10}\frac{T_1}{T_2} \tag{8.1}$$

where $T_1 = 1$ s (reference duration for SEL values) and T_2 = duration of the seismic pulse, in our case 50 ms (see review OSPAR, 2009).

After this formula, RMS values could be derived by adding 13 dB to the corresponding SEL values. The differences between the peak and the peak-to-peak value were set at 6 dB.

Table A2-4 Summary of source levels for the 4 x 40 in^3 airgun array used in the acoustical modelling

Variable	Dimension
Peak-to-Peak source sound pressure level	236 dB re 1 µPa
Zero-to-peak source sound pressure level	230 dB re 1 µPa
Source sound pressure level	227 dB re 1 µPa
Sound exposure level at 1 m	214 dB re 1 µPa^2·s

For the present study, the array layout was comparably simple. We thus opted for a conservative approach with the directivity of the seismic array defined as omnidirectional, i.e. the same noise radiated in all azimuth angles.

3.3.2 Sound propagation modelling

The calculation of the sound levels at different distances from the sources was undertaken for frequencies up to 4 kHz using a numerical model of the underwater acoustic propagation. For this end we used the well-established AcTUP package (Duncan and Maggi, 2006). We applied the RAMGeo code which is a full Parabolic Equation model. RAMGeo is based on the RAM[3] approach and was developed by Collins (1993) applying Padé series expansion. RAMGeo accounts for the change in speed of sound in the water column.

The sea surface is treated as a simple, perfectly reflecting boundary modelled as a pressure-release boundary. For a realistic treatment of seabed effect on wave propagation in the ocean, it is necessary to include absorption in the bottom material. The model includes propagation in the bottom seabed, but only handles compression waves (ocean bottom sediments modelled as fluids) not shear waves. Besides accounting for attenuation constants in the bottom layers, it is important to include density changes at the water-bottom interface as well as within the bottom itself for a realistic treatment of bottom effects on propagation. A simplified bottom description based on a number of constant-density layers was used. The lower boundary condition involves termination of the physical solution domain by an artificial absorption layer of several wavelengths thickness so as to ensure that no significant energy is reflected from the lower boundary. The absorption layer is modelled with a complex index of the refraction model.

The sound source properties of the airgun array were combined with the propagation model to calculate the sound propagation in discrete angular directions of the seismic array at 10 2D transects. We modelled specific 1/3 octave bands from 10 Hz to 4 kHz that are most relevant for the marine mammal species in the area. Based on our calculations we will provide exemplary maps of the sound pressure field as a function of distance (full maps in Appendix A). These ‘noise maps’ will be used for the impact assessment in the next step. In total, we have 3 positions of the seismic survey vessel and calculate the sound spread for each position (e.g. 3 noise events simulated times 10 acoustic propagation transects = 30 calculations).

As the three most important species in the region (walrus, beluga whale and narwhal) spend most of their time in the upper water column, the receiver depth[4] was set at 20 m in the modelling of the transmission loss of the 1/3 octave frequencies.

The Range-dependent Acoustic Model simulations were carried out based on the following simplified conditions and specific assumptions:

- The sea surface is treated as a simple, horizontal perfectly reflecting boundary ignoring the sea states, where in addition to waves the upper ocean will have an infusion of air bubbles which has a significant impact on the speed of sound in the surface part of the water column. Furthermore, the ocean surface of the area of investigation is assumed to be completely free of ice including the present of a partial ice cover and ice floes.
- The code is a 2D model ignoring 3D effects due to horizontal refraction of sound rays reflected by a sloped sea bottom. E.g. when the sea floor is shoaling, as is the case for the ocean over a sloping beach and the continental slope, and around seamounts and islands, a ray travelling obliquely across the slope experiences the phenomenon of horizontal refraction.
- Effects of underwater ambient noise and masking are not addressed in the model.
- Airguns arranged in arrays are tuned to focus sharply pulsed pressure downward into the ground. Thus energy emission and propagation in the horizontal are reduced. In the present numerical model the source is modelled as a point source, which is omni-directional. At low-frequencies, below a few hundred Hz, the sound source characteristics of an airgun appear omni-directional, however, each airgun becomes more multipolar with higher frequency. The extent of the airgun array and the directionality of the sound source are ignored in the noise propagation simulations.

[3] Range-dependent Acoustic Model (RAM)

[4] Note the reported levels are at a constant water depth and is not the maximum value in the water column at each discrete distance from the sound source.

The simplifications are expected to lead to a conservative estimate of the sound levels.

The spatial discretisation used in the finite difference model is defined in terms of the wavelength being modelled. Hence the simulations take into account sensitivity to frequency components. The radial resolution is

$$dr = \alpha\lambda \tag{8.2}$$

and the depth resolution is then defined as

$$dz = \beta\, dr \tag{8.3}$$

The modelling was carried out with the following discretisation for the different frequency domains.

Table A2-5 Spatial discretisation parameters for different frequency regions

Frequencies	α	β	Number of Padé tems
1 Hz - 50 Hz	$\frac{1}{40}$	2	8
51 Hz - 200 Hz	$\frac{1}{10}$	2	8
201 Hz - 1000 Hz	$\frac{1}{5}$	2	8
1001 Hz - 4000 Hz	$\frac{1}{5}$	2	8

In the sound propagation simulation at frequencies above 1 kHz the effect of the bathymetry surrounding the source is ignored.

3.4 Threshold values

For the quantitative assessment of impact ranges, we have chosen several criteria for marine mammals and fish that have been derived from a variety of sources (see NMFS, 2003; Southall et al., 2007; Halvorsen et al., 2011). The NMFS criteria are part of the US regulation (except, to our knowledge, the behaviour criteria), although depicting pulsed sounds in rms sound pressure levels is not without its problems (see discussion by Madsen, 2005). The NMFS criteria are based on the assumption that received levels that are lower than these criteria will not injure animals or impair their hearing abilities but higher received levels may have some effects. We have interpreted these criteria as the onset of TTS also noting the relative low values. Applicable are the initial scientific recommendations on marine mammal noise exposure criteria as developed by a group of US experts (Southall et al., 2007). Recent work on fish has resulted in evidence based criteria for this taxa (Halvorsen et al., 2011).

Table A2-6 provides an overview of noise exposure criteria for marine mammals and fish that have been used in this assessment.

Table A2-6 Marine mammal and fish noise exposure criteria used in the quantitative assessment (PTS = Permanent threshold shift; a permanent elevation of the hearing threshold in certain frequencies. TTS = Temporary threshold shift; a temporary elevation of the hearing threshold in certain frequencies.

Source	Effect	Taxa	Sound type	Sound pressure level / SEL
NMFS, 2003	Start of hearing effects - TTS	Cetaceans	Airgun pulses	180 dB re 1µPa
	Start of hearing effects - TTS	Pinnipeds	Airgun pulses	190 dB re 1µPa
Southall et al., 2007	PTS	Cetaceans (3hearing classes)	Single - multiple pulse	230 dB re 1µPa peak
	PTS	Cetaceans (3 hearing classes)	Single - multiple pulse	SEL 198 dB re 1µPa^2-s (M_{lf}, M_{mf}, M_{hf})
	PTS	Pinnipeds (in water)	Single pulse - multiple pulse	218 dB re 1µPa peak

Southall et al. 2007	Response	Seals	Multiple pulses	190 dB re 1µPa

4. RESULTS

The following section presents the results of the simulations. First we present a brief description of how the different values are determined, followed by tabulated ranges to threshold values and finally exemplary plots of the sound propagation.

The following section presents the results of the simulations. First we present a brief description of how the different values are determined, followed by tabulated ranges to threshold values and finally exemplary plots of the sound propagation.

4.1 Sound levels

The output from the modelling in AcTUP is the Transmission loss (TL) 1/3 octave per frequency band

$$TL_f = -20\log_{10}\frac{p_{recived}}{p_{source}}\ [\text{dB}] \tag{8.4}$$

This transmission loss is then used to determine the received SEL (SEL^R) at any distance by subtracting the TL from the source level according to (8.5).

$$SEL^R = 10\log_{10}\left(\sum_f 10^{0.1\,SEL_f^{SRC}-0.1\,TL_f}\right) \tag{8.5}$$

Where SEL_f^{SRC} is the SEL for each 1/3 octave band with the centre frequency f. See source spectrum in Figure A2-6.

The M-weighted SEL is found as

$$SEL = 10\log_{10}\left(\sum_f 10^{0.1\,SEL_f-0.1\,M(f)}\right) \tag{8.6}$$

where the weighting factor is determined as

$$M(f) = -20\log_{10}\left(\frac{f^2 f_{hi}^2}{(f^2+f_{lo}^2)(f^2+f_{hi}^2)}\right) \tag{8.7}$$

where the cut-off frequencies are as listed in Table 3.1.

The weighting curves are plotted in Table A2-7.

Table A2-7 Functional hearing groups and associated auditory bandwidths (Southall et al. 2007)

Functional hearing group	Estimated auditory bandwidth	
	f_{lo}	f_{hi}
Low-frequency Cetaceans (LFC)	7 Hz	22 kHz
Mid-frequency Cetaceans (MFC)	150 Hz	160 kHz
High-frequency Cetaceans (HFC)	200 Hz	180 kHz
Pinnipeds (PINN)	75 Hz	75 kHz

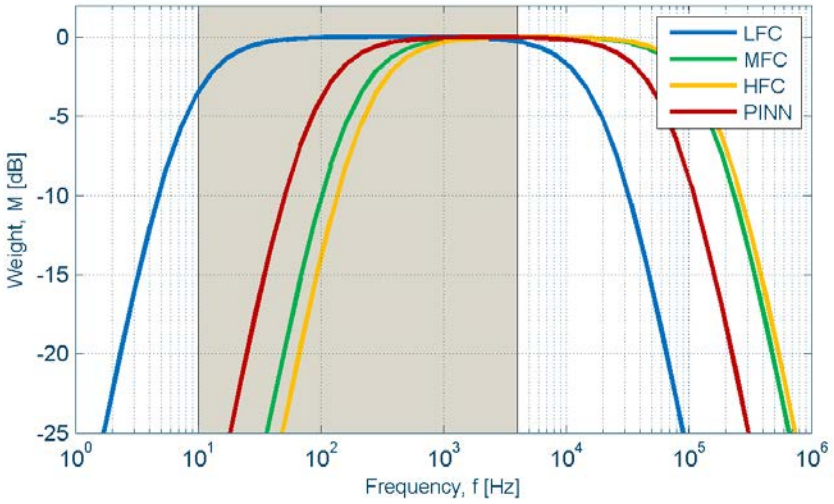

Figure A2-7 M-weights. The shaded area marks the modelled frequency area.

The overall received SEL level from (8.5) is used to determine an *overall* transmission loss

$$TL_{oa} = SEL_{oa}^{SRC} - SEL_{oa}^{R} \text{ [dB]} \tag{8.8}$$

Which is used to determine the received SPL_{peak} and SPL_{rms} values

$$SPL^{R} = SPL^{SRC} - TL_{oa} \tag{8.9}$$

This is done under the assumption that the shape of the frequency spectrum of SEL and SPL is equal.

4.2 Single shot distance to threshold levels

The following tables present the ranges in where a sound level above the given threshold is present. The ranges are determined as the maximum range as well as the mean range in the simulation of the 10 azimuthal traces.

Table A2-8 Distance to M-weighted SEL thresholds at each site (note: '-' no record in the modelling of any distance referring to the sound level so no evidence of impact (range $\lesssim 10$ m)).

M-weighted SEL (dB re 1 µPa²·s)	Distance to threshold level Location 1		Distance to threshold level Location 2		Distance to threshold level Location 3	
Source SEL = 214 dB	R_{max} (m)	R_{mean} (m)	R_{max} (m)	R_{mean} (m)	R_{max} (m)	R_{mean} (m)
198 M (LFC)	-	-	-	-	-	-
198 M (MFC)	-	-	-	-	-	-
198 M (HFC)	-	-	-	-	-	-
187 unweighted (overall SEL level) Fish	-	-	-	-	-	-
186 M (Pi)	-	-	-	-	-	-
183 M (LFC)	30	30	30	21	30	21
183 M (MFC)	-	-	-	-	-	-
183 M (HFC)	-	-	-	-	-	-
171 M (Pi)	50	50	50	50	50	50
140 unweighted	3 630	3 420	3 460	3 447	3 290	3 158

Table A2-9 Distance to SPL thresholds at each site

SPL (dB re 1 µPa)	Distance to threshold level Location 1		Distance to threshold level Location 2		Distance to threshold level Location 3	
Source SPL = 227 dB	R_{max} (m)	R_{mean} (m)	R_{max} (m)	R_{mean} (m)	R_{max} (m)	R_{mean} (m)
200	-	-	-	-	-	-

4.3 Singe shot frequency dependent propagation loss

The subsequent section presents exemplary plots of the SEL from the simulations. In the transect contour plots the noise penetration into the seabed is not shown, although the phenomenon is included in the calculations.

The first plot presents the SEL in terms of the overall SEL as well as the four M-weighted SEL. The second figure is a zoom on the first kilometre. This reveals the very rapid attenuation of the sound levels within the first couple of hundred meters.

The third figure shows the source SEL frequency spectrum together with the received spectrum at 1 km, 5 km, 10 km, 50 km and 100 km from the source.

The fourth and final plot shows a two-dimensional transect of the SEL. The shaded area indicates the seabed.

We have chosen a single direction for each of the three locations, with different development in the bathymetry for illustration purposes.

4.3.1 Location 1: Direction 144 °N

4.4 Single shot noise maps

The noise maps for single shots are shown in Appendix B. It can be seen that the sound is not spreading omnidirectional due to the interactions with the bathymetry including sound absorption and propagation in the seabed. It is visible too; that the sound is degrading to relatively low levels close to receiver, although it will most likely be audible to marine life over the entire license block area with 105 dB re 1 $\mu Pa^2 \cdot s$ most likely exceeding ambient noise levels in most cases. It is visible also that the horizontal sound spread differs across regions but that the overall distribution of received sound exposure levels looks very similar between the three locations.

4.5 Cumulative SEL maps

Cumulative SEL has been used to assess the noise exposure for marine mammals exposed to multiple pressure pulses from the airgun array, with resulting impact ranges larger than for single shot.

As there are no other surveys occurring in 2013, only the Shell survey has been used to calculate the cSEL levels.

The cumulative sound exposure is calculated as

$$SE_{cum} = SEL_{single} + 10\log_{10} n \tag{8.10}$$

where n is the number of shots fired during a period of 24 hours at a single location. n=15,000. Hence the cumulative sound exposure level is 41.7 dB higher than the single shot SEL.

The maps for the cumulative footprint of the survey are shown in Appendix C. The horizontal spread of the sound is identical to the broadband levels but the overall received levels are higher compared to the broadband levels for the single shot.

5. CONCLUSIONS

In the present study the noise propagation from a seismic survey at three locations in the Baffin Bay area using an air-gun array was modelled. Detail site-specific input data was used in the simulations. The modelling is done in frequency domain for all 1/3-octave band frequencies between 10 and 4000 Hz. All calculations are done on a deterministic basis, hence the model does not account for ocean dynamics due to surface waves, currents, fluctuations in the sound speed profile arising from small-scale turbulence, etc. The results presented are to be viewed in light of an ensemble averaged basis.

On average the simulations show that the sound propagation across the three locations are similar, leading to very similar results with regards to the range over which impacts on marine life might occur.

Most of the acoustic energy of the seismic airgun pluses is located well below 1 kHz with the higher frequencies attenuating more rapidly than the lower ones. As attenuation due to viscosity reduces with decreasing frequency, low frequency propagation in the Deep Sound Channel can extend over vast distances in the ocean.

From the numerical calculations it is also apparent that the transmission loss is very high over the first km from the source which is in principal in line with expectations (see Jensen et al., 2011), although the level of decrease over the first few hundred meters is very high. In the far field, the sound propagates with much less loss compared to the near field.

As the difference between the three sites show very little variation in sound exposure level it is expected that the results obtained here very likely can be transferred somewhat to other sites if the development is relocated.

As expected, the computations show that the cumulative sound[6] results in higher impact ranges than for single shots. Yet, the assumption that the acoustic energy just sums up at the receiver in the way suggested by Southall et al., 2007, neglects that hearing might recover between pulses. Thus, the overall impact from the survey over the course of a one-day cycle might be smaller than indicated in the cumulative maps.

APPENDIX 3
SUMMARY OF CALCULATIONS FOR ESTIMATES OF PERCENTAGE OF POPULATIONS AND NUMBER OF INDIVIDUALS EXPOSED TO SEISMIC NOISE

Estimates of animals assessed to be physiologically impacted from the seismic surveys have been assessed, providing a percentage of the population assessed to be potentially impacted. The calculation has been performed in line with the 2012 EIA, for the following species:

- Ringed seal
- Narwhale (offshore)
- Beluga whale
- Bowhead whale
- Walrus

The assessment has been made based on the population and density estimates performed for the 2012 EIA for seismic activities in the two license blocks (EIA reference /6/) and the zones of impact assessed defined in the acoustic modelling.

The impact zones and subsequent estimates have been prepared without considering mitigating efforts, and therefore take a precautionary approach. As described in this EIA, for the 2D high resolution surveys TTS will be limited to areas close to the source (80 m in cetaceans and 40 m for pinnipeds). Behavioural response is expected in cetaceans (narwhals, beluga whales and bowhead whales) at ranges up to 6 km from the source, while seals are much less affected with behaviour to be expected less than 100 meters from the source.

The number of ringed seal and narwhals potentially exposed to each level of seismic sounds was estimated by multiplying the impact zones by the density of animals. The estimated numbers were then divided by the population size to estimate the proportion of the population exposed.

Table A3-1 Estimates of individuals and percentage of population of ringed seal and narwhale assessed to potentially be physiologically impacted.

	Density	Corrected density[a]	Estimated population size	Impact zone	Animals assessed to be physiologically impacted (TTS)	
	individuals /km^2	individuals /km^2	individuals	km^2	Individuals[b]	Percentage of population[c]
Ringed seal	1.39		228,000	0.005	7.0E-03	3.1E-06
Narwhale (offshore)	0.0026	0.0122	15,060	0.020	5.2E-05	3.5E-07

[a] corrected for availability bias by dividing by 0.21 (CV=0.09)

[b] density * impact zone

[c] impacted individuals / population * 100

Table A3-2 Estimates of individuals and percentage of population of ringed seal and narwhale assessed to potentially be behaviourally impacted.

	Density	Corrected density	Estimated population size	Impact zone	Animals assessed to be behaviourally impacted	
	individuals /km^2	individuals /km^2	Individuals	km^2	Individuals[1]	Percentage of population[2]
Ringed seal	1.39		228,000	0.005	7.0E-03	3.1E-06
Narwhale (offshore)	0.0026	0.0122	15,060	113	2.9E-01	2.0E-03

[a] corrected for availability bias by dividing by 0.21 (CV=0.09)

[b] density * impact zone

[c] impacted individuals / population * 100

For the other marine mammals, only an estimate of the percentage of the population, as the distributions of these species (beluga whale, bowhead whale, walrus, and polar bear) are not expected to overlap in any substantive way with the seismic survey. The percentage was determined by dividing the impact zone by the size of the Baffin Bay Strategic Environmental Assessment Study Area.

For belugas, the assessment was performed for both summer and fall. In the case of the summer beluga estimate, this number was further multiplied by 0.01 to account for the fact only 1% of the population could still occur in the Baffin Bay SEIA Study Area. When considering the fall migrating beluga estimate, this number was multiplied by 0.1 to account for the fact that only 10% of the population could still occur beyond 5 km from the coast during the migration.

Table A3-3 Estimates of percentage of population of beluga, bowhead whale and walrus assessed to potentially be behaviourally impacted.

	SEIA Assessment Area	Percentage of the population available	Impact zone	Animals assessed to be behaviourally impacted
	km^2	**%**	km^2	Percentage of population[a]
Beluga whale				
Summer (July–September)	163,845	1	0.020	1.2E-07
Fall (October)	163,845	10	0.020	1.2E-06
Bowhead whale	163,845	100	0.020	1.2E-05
Walrus	163,845	100	0.005	3.1E-06

[a] (Impact zone/Area) x percentage of the population available

Table A3-4 Estimates of percentage of population of beluga, bowhead whale and walrus assessed to potentially be behaviourally impacted.

	SEIA Assessment Area	Percentage of the population available	Impact zone	Animals assessed to be behaviourally impacted
	km^2	**%**	km^2	Percentage of populationa[a]
Beluga whale				
Summer (July–September)	163,845	1	113	6.9E-04
Fall (October)	163,845	10	113	6.9E-03

Redefining Walrus Stocks in Canada

ROBERT E.A. STEWART[1]

(*Received 7 May 2007; accepted in revised form 21 December 2007*)

ABSTRACT. Defining management units is basic to the sound management of resources. Walrus (*Odobenus rosmarus rosmarus*) are hunted throughout their range in Canada and are subject to other human activities requiring management decisions. Current management units are based on a comprehensive review and a stock assessment completed in the mid 1990s. Between 1993 and 2004, satellite-linked radio tags provided information on the movements of walrus in Canada's High Arctic. These data were incorporated with other information that has become available since 1995 to reassess walrus management units in Canada. Tagging data and other information suggest that some finer discrimination of walrus populations is needed as a precautionary approach and to formulate testable hypotheses. Specifically, the previous North Water/Baffin Bay walrus stock may be considered to be three stocks: Baffin Bay, west Jones Sound, and Penny Strait-Lancaster Sound stocks. The Foxe Basin population appears to comprise two stocks (North Foxe Basin and Central Foxe Basin) rather than one. Previously suspected subdivisions in the Hudson Bay-Davis Strait population are substantiated by isotopic evidence although sampling on a finer geographic scale is required before this stock can be partitioned. There is new evidence to support the previously postulated separation of the walrus in the Southern and Eastern Hudson Bay stock from all others, but no evidence to warrant subdivision.

Key words: walrus, *Odobenus rosmarus*, satellite tag, genetic, isotope, contaminant

RÉSUMÉ. La définition des unités de gestion est fondamentale à la bonne gestion des ressources. Le morse (*Odobenus rosmarus rosmarus*) est chassé dans son aire d'extension au Canada, en plus d'être assujetti à d'autres activités humaines nécessitant des décisions en matière de gestion. Les unités de gestion actuelles sont fondées sur l'examen exhaustif et l'évaluation des groupes effectués vers le milieu des années 1990. Entre 1993 et 2004, des étiquettes radio par satellite ont fourni des renseignements sur les mouvements du morse dans le Grand Nord du Canada. Ces données ont été intégrées à d'autres informations disponibles depuis 1995 dans le but de réévaluer les unités de gestion du morse au Canada. Les données obtenues grâce aux étiquettes et d'autres informations laissent croire qu'il y a lieu d'avoir une discrimination plus raffinée des populations de morse en tant qu'approche de précaution et de formuler des hypothèses pouvant être mises à l'épreuve. Plus précisément, l'ancien groupe de morses des eaux du Nord et de la baie de Baffin peut être considéré comme trois groupes, soit les groupes de la baie de Baffin, du détroit Jones de l'ouest et des détroits de Penny et de Lancaster. Par ailleurs, la population du bassin Foxe semble comprendre deux groupes (le bassin Foxe du nord et le bassin Foxe du centre) au lieu d'un seul groupe. Les sous-divisions dont on se doutait auparavant pour ce qui est de la population de la baie d'Hudson et du détroit de Davis sont corroborées par des preuves isotopiques, quoiqu'un échantillonnage plus perfectionné s'avère nécessaire à l'échelle géographique avant que ce groupe ne puisse faire l'objet d'une répartition. Il y a de nouvelles preuves permettant de soutenir l'ancienne séparation hypothétique des groupes de morses dans le sud et l'est de la baie d'Hudson par rapport à tous les autres groupes, mais aucune preuve ne vient justifier une sous-division.

Mots clés : morse, *Odobenus rosmarus*, étiquette par satellite, génétique, isotope, contaminant

Traduit pour la revue *Arctic* par Nicole Giguère.

INTRODUCTION

In fisheries science, management units are often referred to as stocks, and managing organizations (e.g., DFO, 2001; NMFS, 2001) carry out stock assessments to determine stock status. Atlantic walrus (*Odobenus rosmarus rosmarus*) in Canada are the subject of such stock status assessments (DFO, 2000).

Historically, walrus occupied Canadian waters from Nova Scotia to perhaps 85° N and from the boundary with Greenland to roughly 100° W, but their range now is less extensive and more discontinuous (Born et al., 1995). Walrus breed in winter, between January and April (Born et al., 1995; Stewart and Fay, 2001), in restricted areas of open water or polynyas (Finley and Renaud, 1980; Stirling et al., 1981). Within their summer range, walrus are segregated by age and sex (Born et al., 1995), with mature males forming separate groups. In many areas, walrus haul out onto land to rest, but they also rest on floating ice.

Here I consider management units of walrus in Canada as the foundation for making management decisions affecting hunting and other human activities. I start by

[1] Department of Fisheries and Oceans, Freshwater Institute, 501 University Crescent, Winnipeg, Manitoba R3T 2N6, Canada; Robert.EA.Stewart@dfo-mpo.gc.ca

© The Arctic Institute of North America

reviewing conceptual aspects of defining management units and then examine the stock structure proposed by Born et al. (1995) that has been applied to recent walrus assessments (DFO, 2000). On the basis of isotopic profiles, Outridge et al. (2003) indicated that some of the stocks proposed by Born et al. (1995) should be further subdivided. I review published data on distribution, hunting availability, isotope and contaminant profiles, body size, and genetic data, as well as new data from walrus fitted with satellite-linked radio tags.

What is a Stock?

The concept of "stock" is common in fisheries management for making intraspecific subdivisions (usually focusing on the question "Which animals are taken where by whom?") to assist managers in making allocation decisions. But, while the term is prevalent in the literature, the concept of "stock" is not defined rigorously. Outside of fisheries, the word "stock" generally refers to the base from which other groups derive. Thus "stock" is analogous to the stem of a tree rather than its branches, an interpretation constant since at least the 14th century (Booke, 1981). In fisheries, "stock" has been used to delimit groups of fish, from systematic to management units (Booke, 1981).

The Fish and Agriculture Organization of the United Nations considered "stock" and "population" to be synonymous (Jefferson et al., 1993). The evolutionarily significant unit applied to Pacific salmon (*Oncorhynchus* spp.) stock issues was defined as (1) a population that is reproductively isolated and (2) an important part of the species evolutionary legacy (Waples, 1991). Waldman (2005:11) concluded that the first criterion, i.e., a population, is "essentially the definition of a stock." Secor (2005), however, cautioned against this interpretation and considered a stock to be a specific portion of a population in which anthropogenic activity influences population productivity. Two groups may not have different evolutionary potential, but still require management decisions at a lower taxonomic level (Taylor, 1997; Taylor and Dizon, 1999). I consider "stock" to be a subpopulation designation.

For operational purposes, Royce (1972) defined a stock as a management unit, a group of animals capable of independent exploitation or management. "Stock" is therefore defined by its interaction with humans: the segment of the fish population considered with respect to actual or potential utilization (Ricker, 1975).

The operational definition of stock based on anthropogenic interaction has at least three influential consequences. First, the delineation of the stock is dependant on the nature of the interaction. For example, trophy-sized male walrus, the object of sport hunts, may be a different stock than the part of the same population that supports the subsistence hunt in the same area. Trophies are selected on the basis of absolute size, and as long as the number of big males removed does not reduce the productivity of the population (surplus male hypothesis, but see Harris et al., 2002; Singer and Zeigenfuss, 2002), the number of animals available for subsistence hunting will not change. The edible walrus products of trophy-kills return to the subsistence consumers, so the sport hunt is not considered additive. This concept, a familiar one in wildlife management, is evidenced in different hunting seasons or bag limits for males and females of a species in one hunting district. However, the term "stock" is used infrequently by wildlife managers, who tend to get by with "demes" and "populations" (see for example Novaks et al., 1987; Harris et al., 2002).

Second, with respect to removals by hunting, the interaction basis for defining stocks means that if one has biological information on every landed walrus at a community, one has the definition of that hunted stock (except for killed and lost animals) at that location. Statistical differences in one or more parameters between harvests mean they are different stocks, or different harvest stocks (Waldman, 2005). Offsetting this advantage is the first influential consequence: sampling by biologists taking biopsies, for example, is an interaction quite different from hunting and may not accurately represent the intraspecific group that will enter the harvest stock.

Third, the perception of "stock" depends on the character set used to differentiate it (Ihssen et al., 1981; Waldman, 2005). Genetic data provide insights into population identity reflecting not only current distribution, but also ancestral patterns that may not relate to existing conditions (Swain et al., 2005; Waldman, 2005). Moreover, selective removal can alter gene flow and enhance population differentiation (Harris et al., 2002), and comparison of neutral genetic markers may not reflect locally adaptive traits or differences (Swain et al., 2005). Population parameters, behaviour, morphology, and meristics, to name a few methods, all present different views of the group being studied. Contaminant profiles and stable isotope signals used to identify stocks indicate that one group of animals lived its life—sampled its environment—differently than the other group (Outridge and Stewart, 1999; Innes et al., 2002; Outridge et al., 2003; Campana, 2005). These are real stock differences; removing animals at one locale characterized by certain chemicals may not affect the number of animals at another locale with different chemical profiles. Clayton (1981) advocated the use of multiple tests employing different types of data, noting that a difference in one type of data was sufficient to differentiate stocks. "A stock is a stock," according to Waldman (2005:12), if a marker discriminates it from other stocks. It is incumbent upon biologists to understand those differences in the context of population structure and ecology. Accepting differences regardless of the nature of the marker also tends to err on the side of conservation: erroneously identifying more stocks than exist is more protective than erroneously pooling stocks that are in fact different (Taylor, 1997; Taylor and Dizon, 1999). Conversely, negative results are not conclusive because other techniques may reveal differences (Waldman, 2005; Wirgin and Waldman, 2005).

Allowing that a stock may not be a self-replicating unit, it becomes important to understand the indirect effects mediated through interbreeding among stocks at the population level, where a population is an intraspecific group more likely to interbreed than to breed with members of another group (Pianka, 1988). Also inherent in this perspective is the separation in time and place that allows site-specific differences to accumulate and persist over time. Simultaneous hunts in separated parts of a walrus population's range may mean there are two stocks, but the distinction requires additional evidence of philopatry to those areas.

The population structure is the fundamental aspect of living resources (Secor, 2005). Population reproductive isolation is often achieved through geographic separation, which was an underlying consideration in the separation of walrus stocks described by Born et al. (1995). The geographic distribution of animals, as opposed to genetic or chemical stock-identifying markers, is something that can be seen in real time. Indeed, aside from trophy walrus, few walrus stocks could be discerned outside of the laboratory. So, if the stock is not a complete, self-sustaining unit but rather a distributional branch of a larger, interbreeding population, managers must return to the population structure and consider both the local group (stock) and the population that supports it (Secor, 2005).

Here I adopt Secor's (2005) definition that a stock is a specific part of a population impacted by human activity in a way that affects population productivity, with Ricker's (1975) caveat to include potential utilization. Therefore, I refer to walrus populations in Canada and assume they are best represented by wintering aggregations when breeding occurs (e.g., Sjare and Stirling, 1996). More widely dispersed aggregations or herds in the open-water season are expected to be segregated by age and sex, with at least female philopatry (Andersen and Born, 2000). Various parts of a population may be removed, sampled, or otherwise impacted at one or more location, and I refer to those aggregations as stocks. This conceptual framework parallels that used for "harvest stocks" of beluga (*Delphinapteras leucas*) by Innes et al. (2002) and of walrus by Outridge et al. (2003), except for the inclusion of summering herds that are not known to be exposed to hunting. It is a model similar to that proposed by Andersen and Born (2000) except that I consider separate breeding groups of walrus to be populations instead of subpopulations.

The final conceptual consideration is the degree of physical separation between two putative stocks. Stock distinctiveness is most easily envisaged when there is a large geographic separation, for example between Foxe Basin and south Hudson Bay walrus. But walrus were once more widely distributed in Canada, and current geographic isolation may be an artefact: isolated groups may be the end points of a once-contiguous distribution characterized not by geographic isolation, but by a cline of differences (Mayr, 1970; Royce, 1972; Gaskin, 1982). Evidence of clinal variation of genotypic and phenotypic characteristics, in which adjacent localities are not statistically different but at some increasing distance (cline width) two samples do differ significantly, may not be apparent outwardly, but is critical to sound management (Taylor and Dizon, 1999). Cline width is often estimated as the distance at which the frequency of the less common marker falls to 20% and the more common marker rises to 80% (Owen and Baker, 2001), or the 20/80 rule (May et al., 1975). Conceivably, with sufficient sampling, it may be possible to measure clinal widths in walrus for management purposes or to reveal structure within a continuous distribution using more powerful statistical techniques (Hoffman et al., 2006). For now, the concept of clinal variation is useful in interpreting the limited information available.

The Hypothesis

Born et al. (1995) identified four putative stocks of walrus in Canada (Fig. 1): North Water (Baffin Bay–Eastern Canadian Arctic); Foxe Basin; Northern Hudson Bay–Hudson Strait–Southeastern Baffin Island–Northern Labrador; and Southern and Eastern Hudson Bay. For brevity, and to base the names, as much as possible, on the relevant water bodies, I use these stock names: Baffin Bay (BB), Foxe Basin (FB), Hudson Bay-Davis Strait (HBDS), and Southern and Eastern Hudson Bay (SEHB). I test these hypothesized stock delineations using new information from satellite-linked radio tags that track movements of individuals and from published data. Born et al. (1995) identified a fifth stock, the West Greenland stock, which is discussed as an adjunct to the HBDS stock.

METHODS

A study area in the western reaches of Jones and Lancaster sounds was selected in which to test, using satellite telemetry, the hypothesis that walrus from Canada were also being hunted in Greenland. In consultation with local communities, terrestrial haulout sites distant from main hunting areas were selected for walrus tagging.

Males and females without calves were selected for attachment of satellite tags. A selected walrus was approached within ~20 m, and an immobilizing drug was administered by a pressurized dart propelled by a CO_2 rifle (Dan-Inject®) (Lanthier et al., 1999). Different immobilizing agents were used over the years (Table 1); the narcotics etorphine and carfentanil (Lanthier et al., 1999) were replaced, first with medetomidine-zolazepam-tiletamine (MZT), then with medetomidine-ketamine (MK) (R.E.A. Stewart and C. Lanthier, unpubl. data). Narcotics were reversed with naltrexone (Lanthier et al., 1999), and the other drugs, with atipamezole.

When the darted walrus was immobilized, neighbouring walrus were displaced to a safe distance by slowly approaching the herd. A satellite-linked transmitter/data collection tag was attached to a tusk with a bonding agent such

FIG. 1. Range of putative walrus stocks in Canada (redrawn from Fig. 3 of Born et al., 1995): 1 Foxe Basin; 2 Southern and Eastern Hudson Bay; 3 Northern Hudson Bay–Hudson Strait–Southeastern Baffin Island–Northern Labrador; and 5 North Water (Baffin Bay-Eastern Canadian Arctic). The numbering used by Born et al. (1995) has been retained (#4 – West Greenland, is outside Canada and has not been labeled).

as epoxy or Ray-Crete® and stainless steel bands. Tag design varied over the course of the study (Fig. 2, Table 1), but all tags except number 11270 (Telonics) were built by Wildlife Computers. Location data were restricted to ARGOS location quality (LQ) 0, 1, 2, and 3, defined by ARGOS as having precision radii of greater than 1500 m, less than 1500 m, less than 500 m, and less than 250 m, respectively (Service Argos, 2007). For each day (local time), the highest LQ was used. If there were several uplinks of maximum LQ in one day, they were averaged for a daily location. LQ 0 data may contain large location errors. LQ 0 data that were more than 1500 m inland were removed from the data set. After generating daily averages, days for which LQ 0 data were the best available were compared to LQ 1–3 data for improbably rapid movement. Location data of quality 1 or better when locations were 24 ± 1 h apart were used to establish a distance criterion (40 km/24 h, see Results). If a daily average LQ 0 location exceeded the distance criterion, the individual data points in the average were examined and extreme values removed until the daily average met the distance criterion or until there were no data for that day.

Relevant tag data are available only for the Baffin Bay stock. The literature was reviewed to obtain other data that might be useful in examining stock definitions for this and other stocks in Canada. Data included, but were not limited to, contaminant levels or signatures, isotopic profiles, disease occurrence or prevalence, and genetic composition. Stock definitions may also reflect the distribution of the human interaction with the stock, and I considered the distribution of approximately 1200 kill sites for walrus harvested between 1996 and 2001 (Priest and Usher, 2004: CD-ROM inclusion). None of the data available sampled the entire range of a putative stock, so the analysis compared point sources of information to determine similarities with or differences from other point sources.

RESULTS AND DISCUSSION

Eighteen tags were deployed between 1993 and 2004 (Table 1). Eleven tags were deployed in fiords on southwest Devon Island, Grinnell Peninsula (Devon Island),

TABLE 1. Tag history of 18 satellite-linked radio tags deployed on walrus between 1993 and 2004. Data are separated into two general areas (Jones Sound and Penny Strait/Lancaster Sound).

and at Brooman Point (Bathurst Island). Seven were deployed in Norfolk Inlet and Goose Fiord adjacent to western Jones Sound (Fig. 3).

There were 16 pairs (7 walrus in 5 years) of tag locations of LQ ≥ 1 approximately 24 h (23.8 ± 0.6, mean + 1 SE) apart. The average distance these tagged walrus moved was 10.8 ± 10.7 km/24 h. The maximum distance moved was 37.8 km in 24 h. Another tagged walrus (2511 in 2003) left a haulout and moved 32.4 km in 14 h, 4.7 km the next day, then 31.0 km to an occupied haulout the third day. Based on this animal and the maximum movement recorded in 24 h, I used 40 km sea distance, multiplied by the number of days for longer periods, to determine if the LQ 0 position was improbably far from adjacent positions. Of the 18 tags deployed, 16 provided at least one location. A total of 1337 locations of LQ ≥ 0 generated 310 daily locations over a maximum of 93 days. Tag data are discussed further in the stock-by-stock analysis that follows. In addition to other studies reviewed in the next sections, I also examined the incidence of diseases that may have been instructive for postulating population separations. Antibodies to canine distemper virus, phocine distemper virus, canine adenovirus, and influenza A antibodies (Duignan et al., 1994; Nielsen et al., 1996, 2000, 2001a; Philippa et al., 2004) did not reveal location differences. Brucella antibodies were not found in small collections of walrus from Grise Fiord (n = 5), Resolute Bay (n = 4) and Nunavik (n = 4), all of the Baffin Bay stock, but were found in Foxe Basin at low frequency (3.2%, n = 157, Nielsen et al., 2001b). Generally, incidence of antibodies was not useful in discerning stock differences.

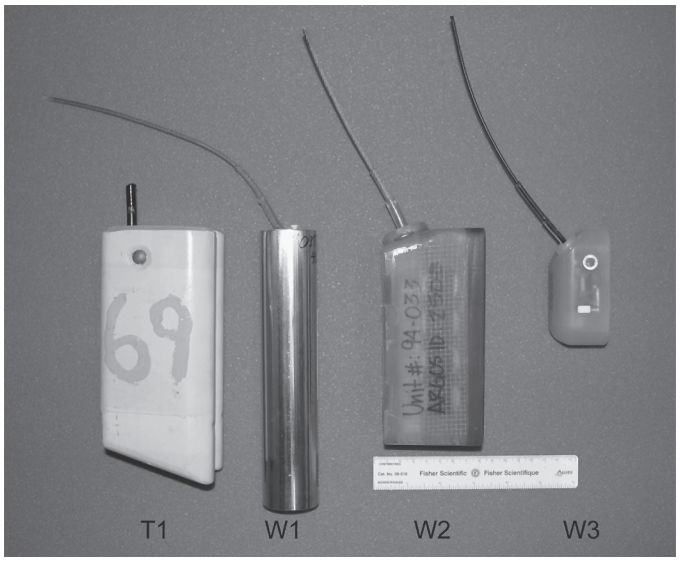

FIG. 2. Satellite radio tags used in this study with the surface contacting the walrus tusk to the right. Left to right: tags from Telonics (T1: 18.7 × 4 × 7.9 cm [length × width × depth], 1503 g) and Wildlife Computers (W1: 19.5 × 4 cm, 612 g; W2: 15 × 5.5 × 7 cm, 772 – 783 g; W3: 8.8 × 4.9 × 3.7 cm, 194 g) deployed on walrus.

Baffin Bay

Wintering areas (Fig. 4) occur in the Cardigan Strait-Fram Sound area at the west end of Jones Sound, around Dundas Island (Born et al., 1995; COSEWIC, 2006), the floe edges of Jones and Lancaster sounds, and in the North Water polynya between approximately 69° and 77° N on the Greenland coast (Born et al., 1995). The degree of separation among wintering areas is not known. Andersen

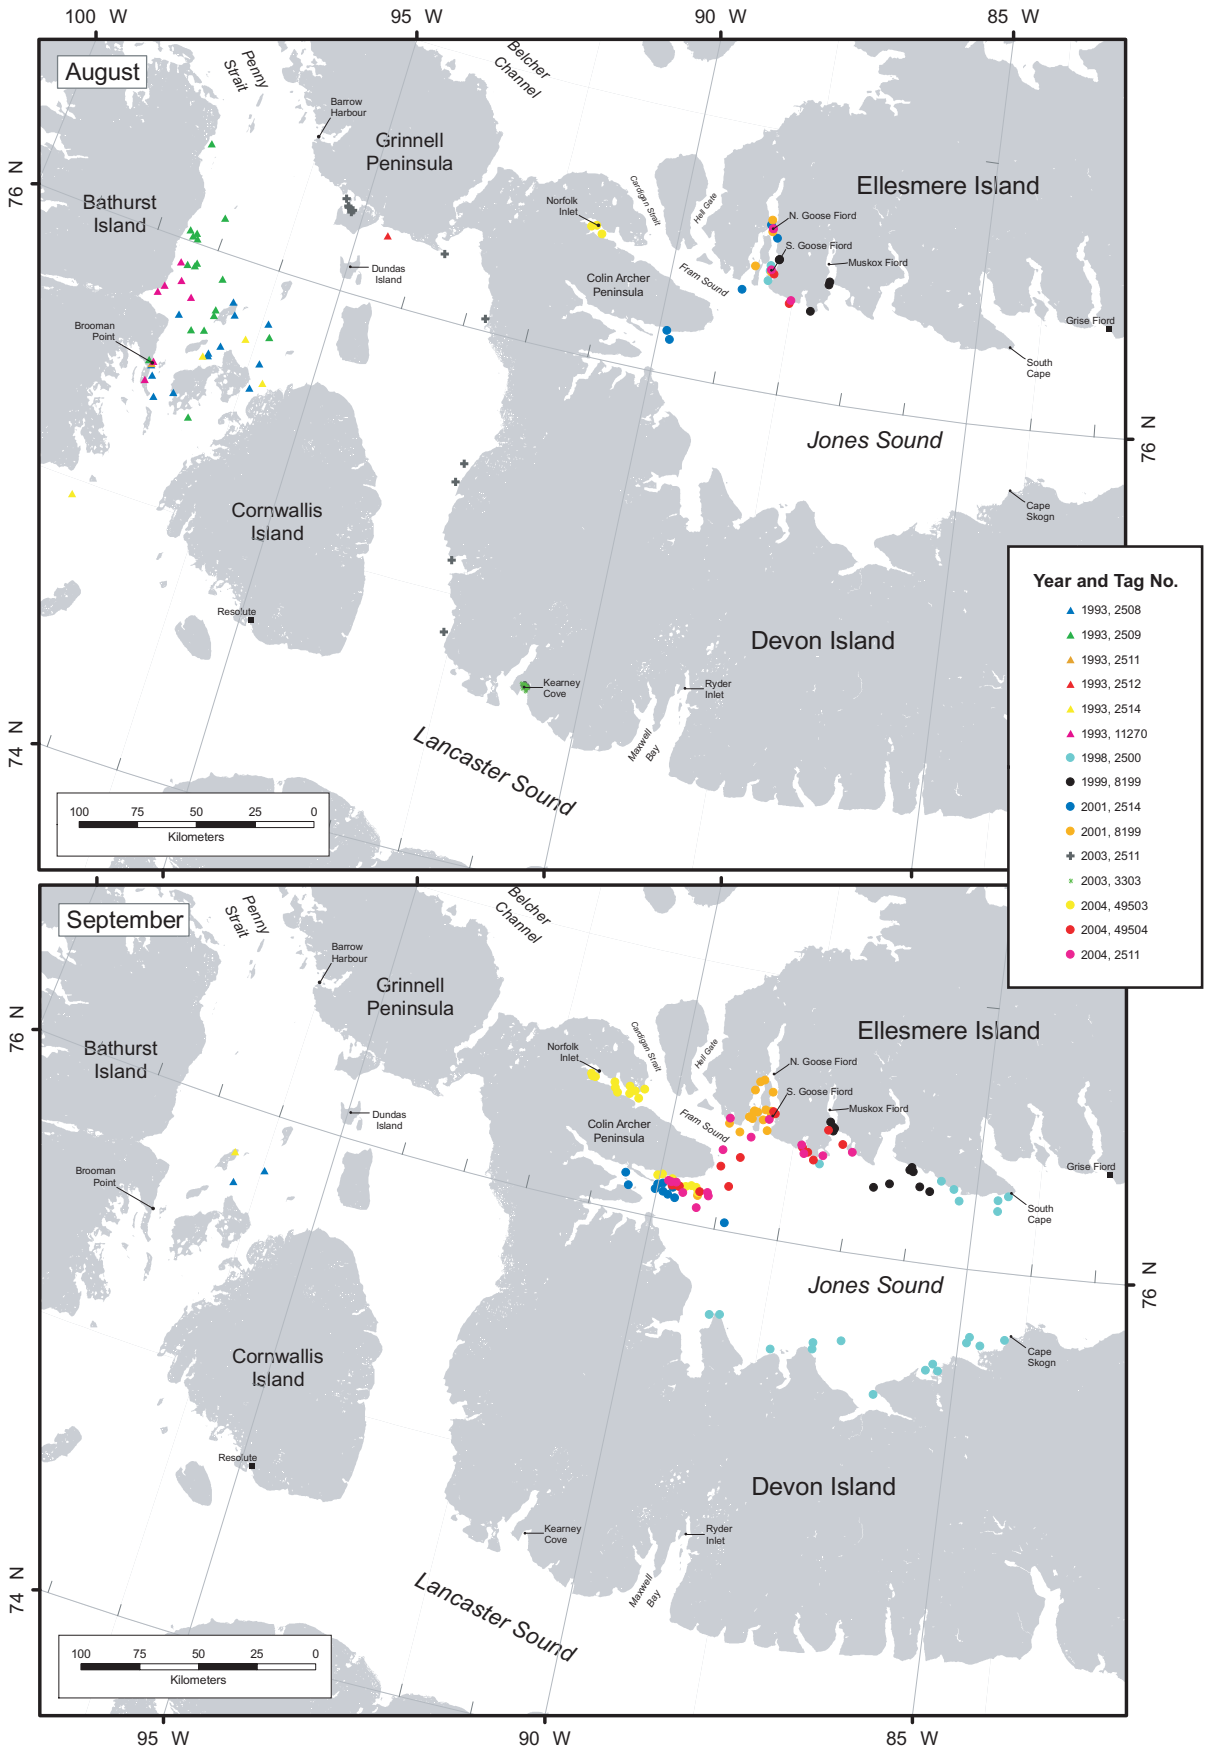

FIG. 3. Sites where satellite tags were deployed on walrus in 1993 and in 1998–2004, as well as daily locations (LQ ≥ 0) for 16 tags that returned data. See Table 1 for the number of tags deployed at each site. This panel: August and September locations.

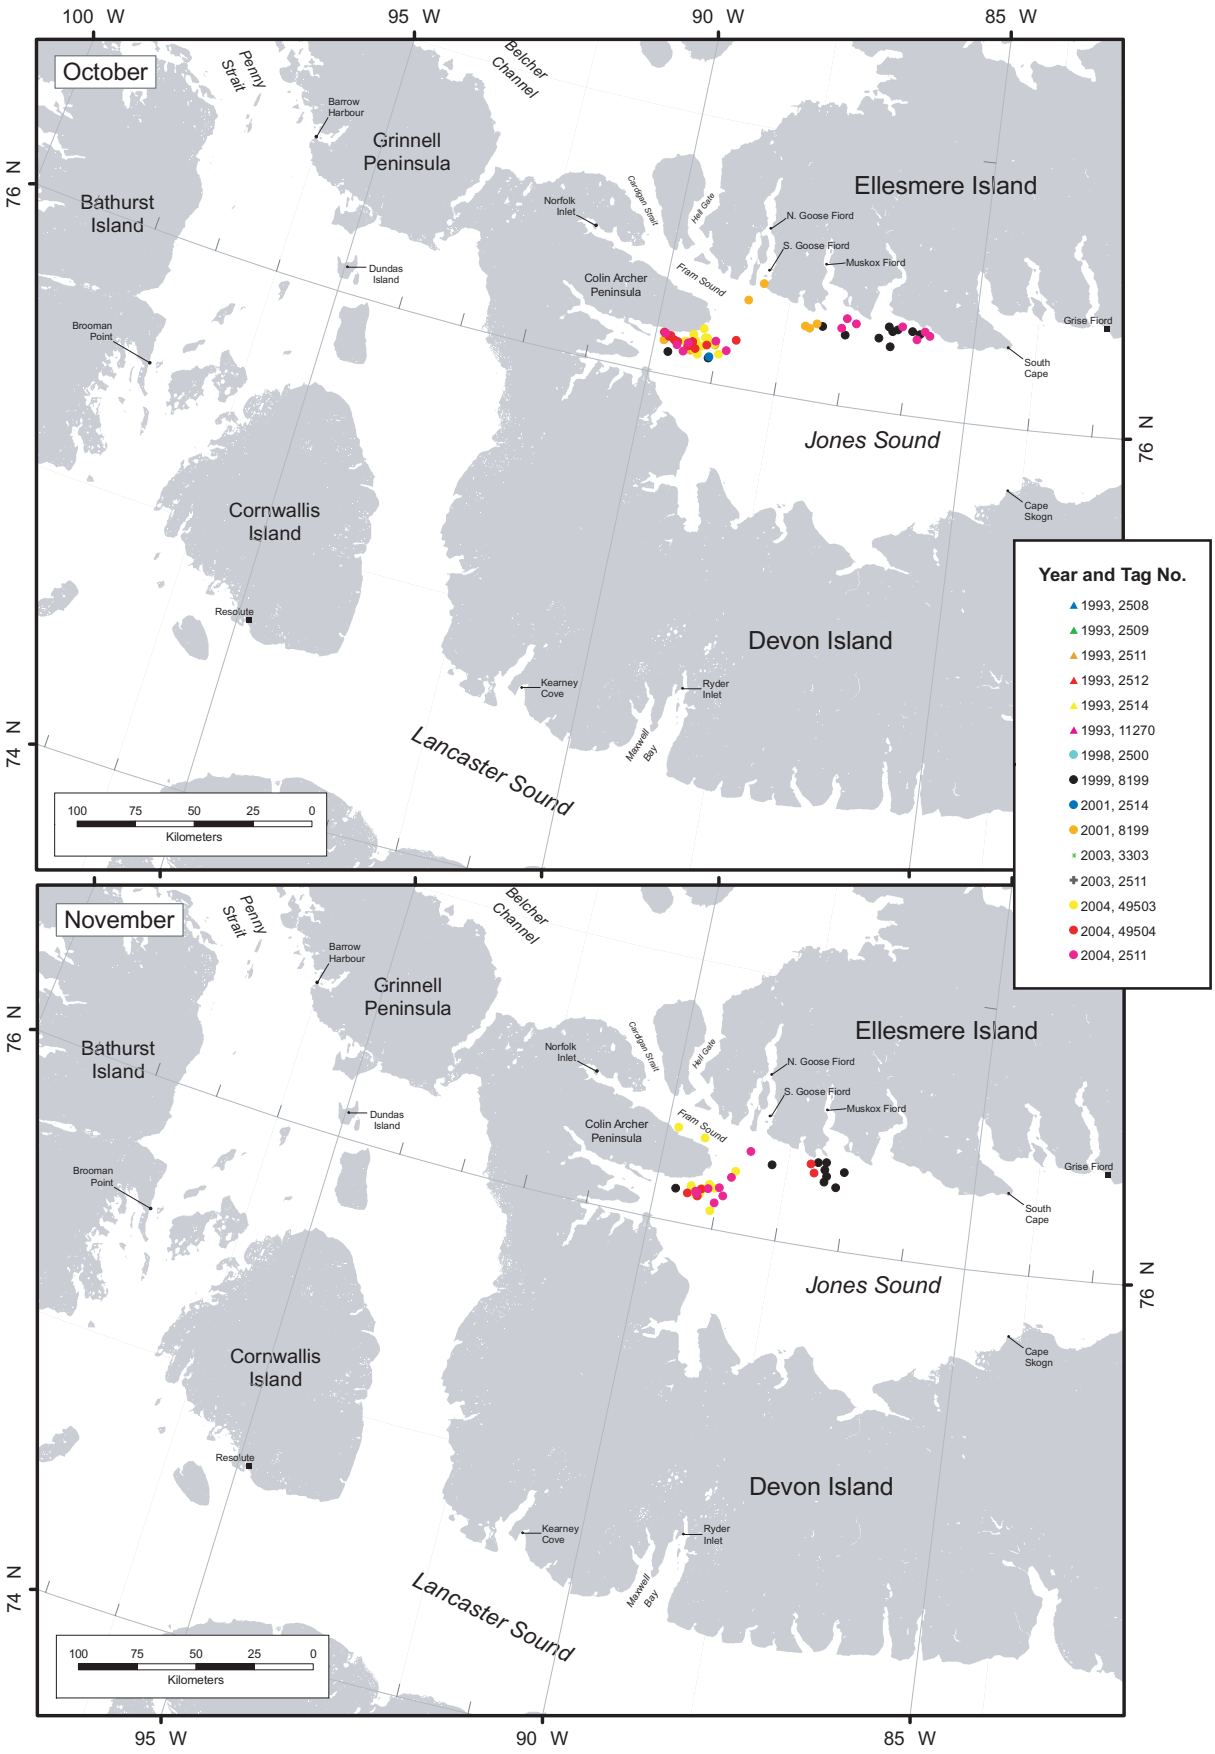

FIG. 3 cont'd. This panel: October and November locations.

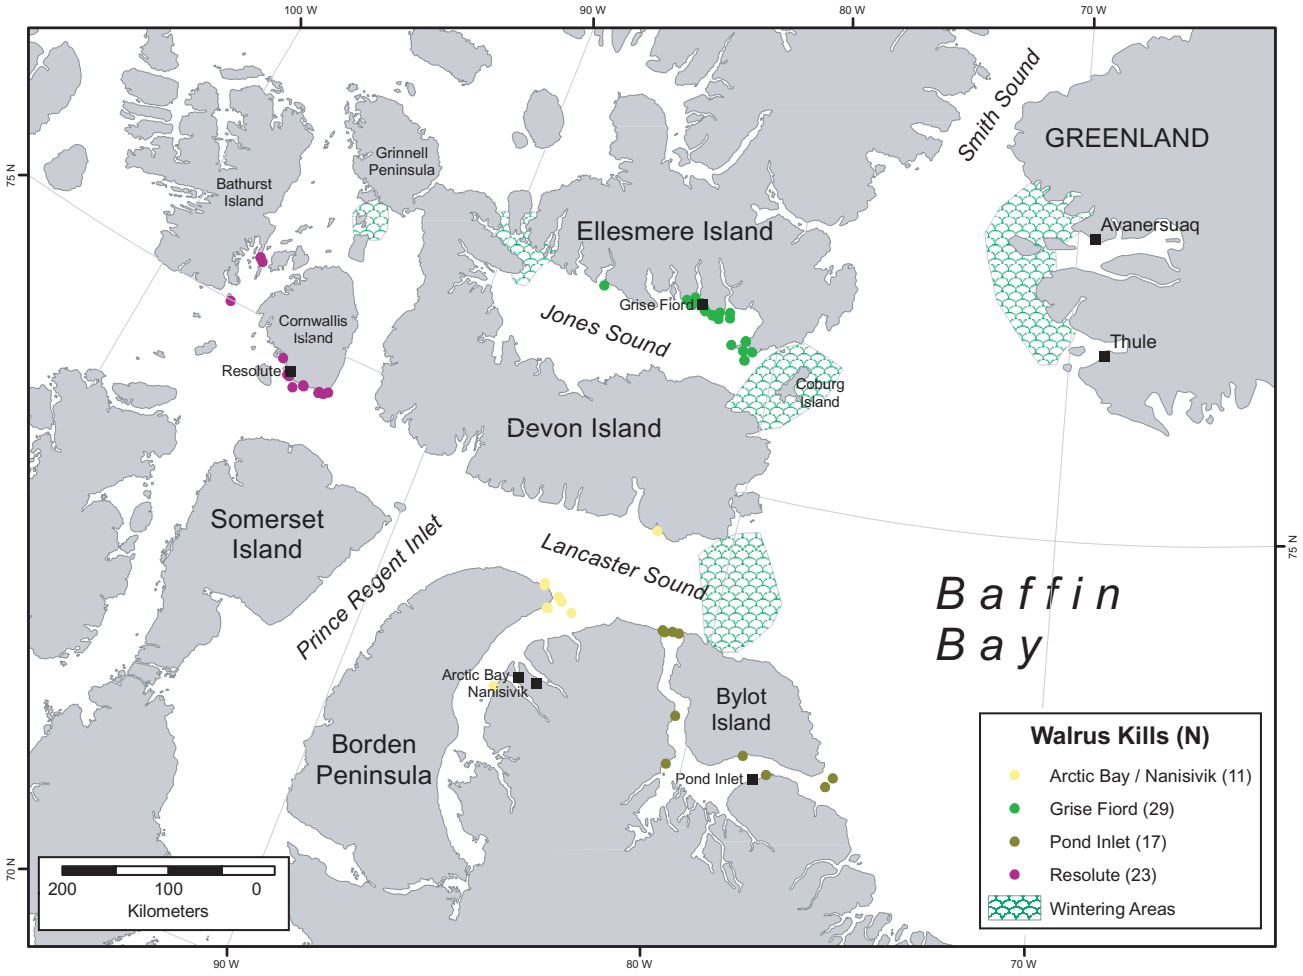

FIG. 4. High Arctic walrus harvesting locations for Grise Fiord, Resolute Bay, Pond Inlet, and Arctic Bay/Nanisivik (Priest and Usher, 2004) and wintering areas (Born et al., 1995). Each kill symbol may represent more than one animal killed; N is the number of walruses reported by each community in the Priest and Usher (2004) database.

and Born (2000) found genetic (mtDNA and microsatellite) differences between walrus landed in North Greenland and West Greenland and proposed that these two wintering groups are separate subpopulations with some male-mediated genetic exchange.

There are no walrus around Avanersuaq between mid-June and mid-July, when they may travel north into Smith Sound or west into Canada (Born et al., 1995). An inductively coupled plasma mass spectrometry (ICP-MS) comparison of lead isotope ratios ($^{206}Pb/^{207}Pb$ and $^{208}Pb/^{207}Pb$) of walrus landed at Grise Fiord and Thule (Outridge et al., 2003) had ambiguous results. There were no significant differences in mean ratios (Outridge et al., 2003), but only eight samples from Grise Fiord were available. However, approximately 80% of the animals at Thule and 20% at Grise Fiord were dissimilar, and the authors concluded that they represent different stocks. This conclusion is consistent with the 20/80 rule (May et al., 1975), but the small sample size at Grise Fiord dictates caution.

Harvest records (Priest and Usher, 2004) indicate hunters from Grise Fiord take walrus near town in August, farther east in September and October, and still farther east, near Coburg Island (Fig. 4), in February to May. Hunters from Pond Inlet hunt walrus in spring at the floe edges in Milne and Pond inlets and in summer farther into these inlets. Hunters from Arctic Bay report most of their harvest from the floe edge of Admiralty Inlet, also in spring. Therefore, walrus that winter at the mouth of Lancaster Sound could be taken in summer either to the north near Grise Fiord or to the south near Arctic Bay, Pond Inlet, and Resolute Bay. The winter hunt from Grise Fiord presumably draws from the group wintering at the mouth of Jones Sound.

None of the walrus, predominantly females, tagged in Norfolk Inlet or Goose Fiord moved farther east than a line between South Cape (~84° 25′ W) on Ellesmere Island and Cape Skogn (~84°10′ W) on Devon Island. Locations in October and November, after freeze-up, were confined largely to the mouth of Muskox Fiord and off the south coast of Colin Archer Peninsula (Fig. 3). Of the 26 hunts (30 walrus landed) recorded from 1996 to 2001, only one took place west of South Cape (Priest and Usher, 2004); most were farther east, at Grise Fiord, Lee Point, and Glacier Strait (Fig. 4). Aerial reconnaissance and local knowledge

also indicate that few walrus are seen between Grise Fiord and South Cape. The distribution of sightings and the tag data suggest that the walrus in western Jones Sound are a different stock than those in the eastern reaches.

Walrus tagged in western Jones Sound did not move through Hell Gate or Cardigan Strait. Exchange with Lancaster Sound walrus from Penny Strait through the Belcher Channel (Fig. 3) appears unlikely. Walrus seen north of Grinnell Peninsula in April 1977 moved west as summer progressed, rather than east towards Hell Gate and Cardigan Strait (Davis et al., 1978). This coastline is low and gradual, and the area is often ice-choked. Overall, the area appears unsuitable for walrus, although these features do not preclude passage by walrus. However, it appears to be an area of separation between a population that winters around Hell Gate and Cardigan Strait and another that winters around Dundas Island.

Walrus that summer in the Lancaster Sound area could be linked to Jones Sound and Foxe Basin stocks (next section). The one female walrus tagged in Penny Strait in August 2003 moved south to the area of Kearney Cove on southwest Devon in early September (Fig. 3). One male of a group of at least 40 males that occupied Kearney Cove at the same time was tagged and remained in that cove, also until early September. All other tags (n = 7) deployed in the areas of southwest Devon and Bathurst Island remained in that general area; none of those walrus travelled north out of Penny Strait or south into Prince Regent Inlet, although all seven tags stopped transmitting before September (Fig. 3), hence before freeze-up. There is no evidence of exchange between Penny Strait and Jones Sound around the west end of Grinnell Peninsula.

Walrus were taken by hunters from Resolute Bay in June to August (Priest and Usher, 2004). These hunters indicate walrus arrive in their hunting area (Fig. 4) from the east in spring. None of the walrus tagged (n = 5) east of Resolute Bay in August moved into the Resolute Bay hunting area that year. There is autumn movement from Penny Strait to Lancaster Sound. One adult male walrus tagged at Bathurst Island in 1993 was killed in June 1994 near Pond Inlet (Stewart, 2002). Another walrus observed at Bathurst Island in 1993 had previously been branded near Dundas Island (B. Sjare, pers. comm. 1993). There is direct exchange from Penny Strait to the mouth of Lancaster Sound, and it is possible that a walrus that summers near Cornwallis Island could winter variously at Dundas Polynya or the mouth of Lancaster Sound.

While there appears to be little or no exchange around the west end of Devon Island, potential mixing of walrus from Lancaster Sound and eastern Jones Sound is less clear. There may be differences in lead isotope ratios determined by ICP-MS between animals at Resolute Bay and those from Grise Fiord and Thule, but small sample sizes precluded statistical comparison (Outridge et al., 2003). More precise thermal ionization mass spectrometry (TIMS) analysis indicated differences between Grise Fiord and Resolute Bay samples, but these could not be compared statistically (Outridge et al., 2003). De March et al. (2002) found no differences among Grise Fiord (harvest, n = 4), Resolute Bay (harvest, n = 9), and Bathurst Island (biopsy, n = 9) samples using microsatellite frequencies and haplotypes. Subsequent microsatellite analysis of larger samples (Grise Fiord, n = 16; Resolute Bay, n = 13, R.E.A. Stewart and L. Postma, unpubl. data) agreed with de March et al. (2002). The differences in isotope ratios and lack of differences in genetic data suggest a single population divided into two stocks, but all the data are preliminary.

These combined data support subdivision of the putative Baffin Bay stock (Born et al., 1995), with the following caveats: genetic data were collected by different methods (biopsy and harvest samples); movement to the proposed wintering area near Colin Archer Peninsula is based on six tags; and females may be more philopatric than males (Andersen and Born, 2000). Adapting NAMMCO (2006) terminology, these newly defined subdivisions are: (1) the Baffin Bay stock, separated from West Greenland by genetic evidence (2) the West Jones Sound (WJS) stock, separated from the Baffin Bay by seasonal distribution and tag movements, and (3) the Penny Strait-Lancaster Sound (PS-LS) stock, separated from West Jones Sound by distribution and tag movements and from Baffin Bay by limited Pb isotope data. Such a stock structure indicates that walrus in the West Jones Sound stock have a much smaller probability of being harvested than was thought. Consequently, harvests in Lancaster Sound, at Grise Fiord, and at Avanersuaq are taken from stocks that are smaller than believed previously. Pb isotope data provide evidence of a cline within the Baffin Bay stock, but further subdivision is not yet possible.

Foxe Basin

Walrus in Foxe Basin generally winter at the floe edge around Rowley Island (Fig. 5) (COSEWIC, 2006). They move to summer areas around islands in northern Foxe Basin and are found routinely on pack ice.

Most walrus hunters in Foxe Basin are from Igloolik and Hall Beach, although hunters from Pond Inlet, Iqaluit, and Arctic Bay/Nanisivik also report landing walrus in Foxe Basin (Fig. 5). Walrus landed at Foxe Basin communities were distinguished from those landed at the HBDS communities of Akulivik, Coral Harbour, Repulse Bay, Loks Land, and Sisimiut (Fig. 6) by differences in lead isotope ratios (Outridge and Stewart, 1999; Outridge et al., 2003). Walrus taken at Akulivik also show differences in organochlorines (Muir et al., 1995). Walrus in Foxe Basin also appear to be larger than those from Hudson Bay (Garlich-Miller and Stewart, 1998). Foxe Basin walrus differ genetically from Baffin Bay walrus in haplotypes and microsatellites (Grise Fiord, Resolute Bay, Bathurst Island; de March et al., 2002) and lead isotope ratios (Grise Fiord, Resolute Bay, Thule; Outridge and Stewart, 1999; Outridge et al., 2003). Movement through Fury and Hecla Strait towards Lancaster Sound is considered unlikely (DFO, 2002).

Stewart et al. (2003) interpreted differences in lead isotope ratios of growth layer groups in the teeth of walrus

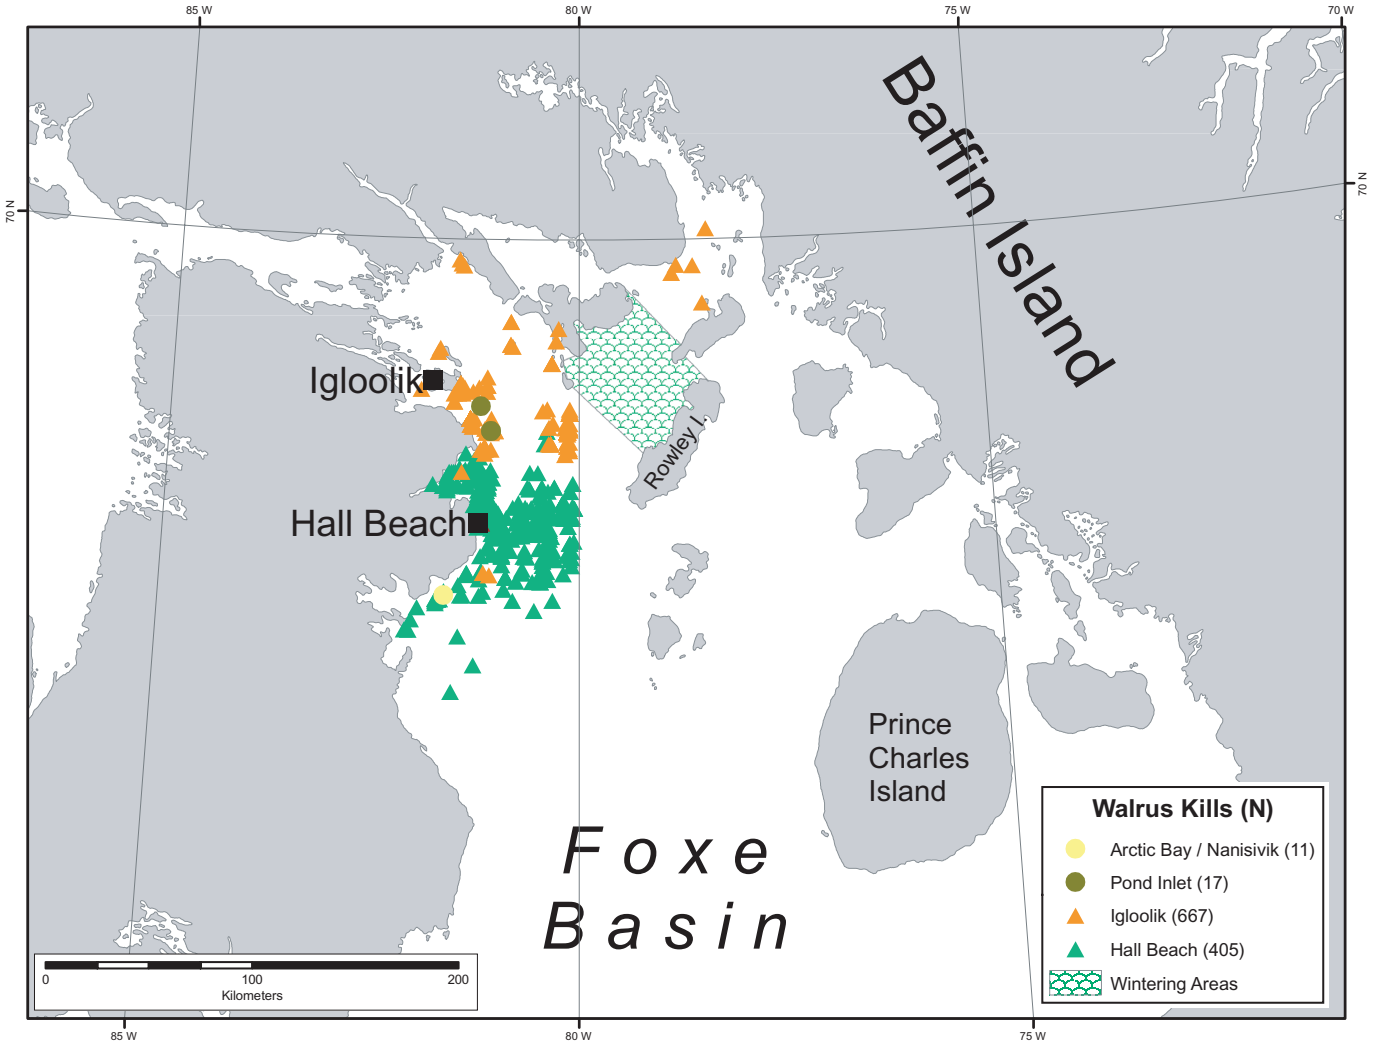

FIG. 5. Foxe Basin walrus harvesting locations for Igloolik and Hall Beach (Priest and Usher, 2004) and wintering areas (Born et al., 1995). Each kill symbol may represent more than one animal killed; N is the number of walruses reported by each community in the Priest and Usher (2004) database.

landed at Hall Beach to indicate changes in the way these male walrus sampled their isotopic environments. Although some of these layers resembled walrus teeth landed at three HBDS communities and one SEHB community, similarity does not prove congruence (Waldman, 2005). For example, walrus from east Greenland and Inukjuak on Hudson Bay have similar lead isotope ratios that reflect common geology, not common distribution (Outridge et al., 2003). Still it is plausible that some males from Foxe Basin moved into other walrus populations nearby and may have reproduced in those populations. Isotope evidence indicated that two of 11 adult males examined had left the Hall Beach area at maturation and returned some years later. Although this potential male-mediated exchange does not refute the conclusion by Born et al. (1995:9) that the Foxe Basin population is "largely isolated from other groups," it does suggest more complex interactions than expected previously.

Walrus landed by hunters at Hall Beach were not distinguishable from walrus landed at Igloolik by genetic (de March et al., 2002), heavy metal (Wagemann and Stewart, 1994), or major organochlorine data (Muir et al., 1995). But Outridge and Stewart (1999) reported differences in lead isotope ratios ($^{206}Pb/^{207}Pb$ and $^{208}Pb/^{207}Pb$) and trace elements even after removal of outliers. Peak landings at Igloolik and Hall Beach overlap in time (Priest and Usher, 2004), but are mostly separated in space (Fig. 5). Simultaneous hunting in two areas suggests two groups of walrus, but philopatry (habitual summering in one or the other area) is required for them to be considered stocks. The hunters from Igloolik take walrus mostly from the northern part of Foxe Basin, where there are areas of Palaeozoic rocks among the predominating Archean geology. The Hall Beach hunting area is underlain by older Proterozoic and Archean geology (Outridge and Stewart, 1999). The differences in isotopic signatures were thus consistent with long-term residency in different geological regimes. Inuit also identify two groups of walrus in this area on the basis of morphology and colour (DFO, 2000).

Therefore, there is evidence of stock separation within Foxe Basin. It is probable that, while landed walrus are from different stocks (the North Foxe Basin and Central

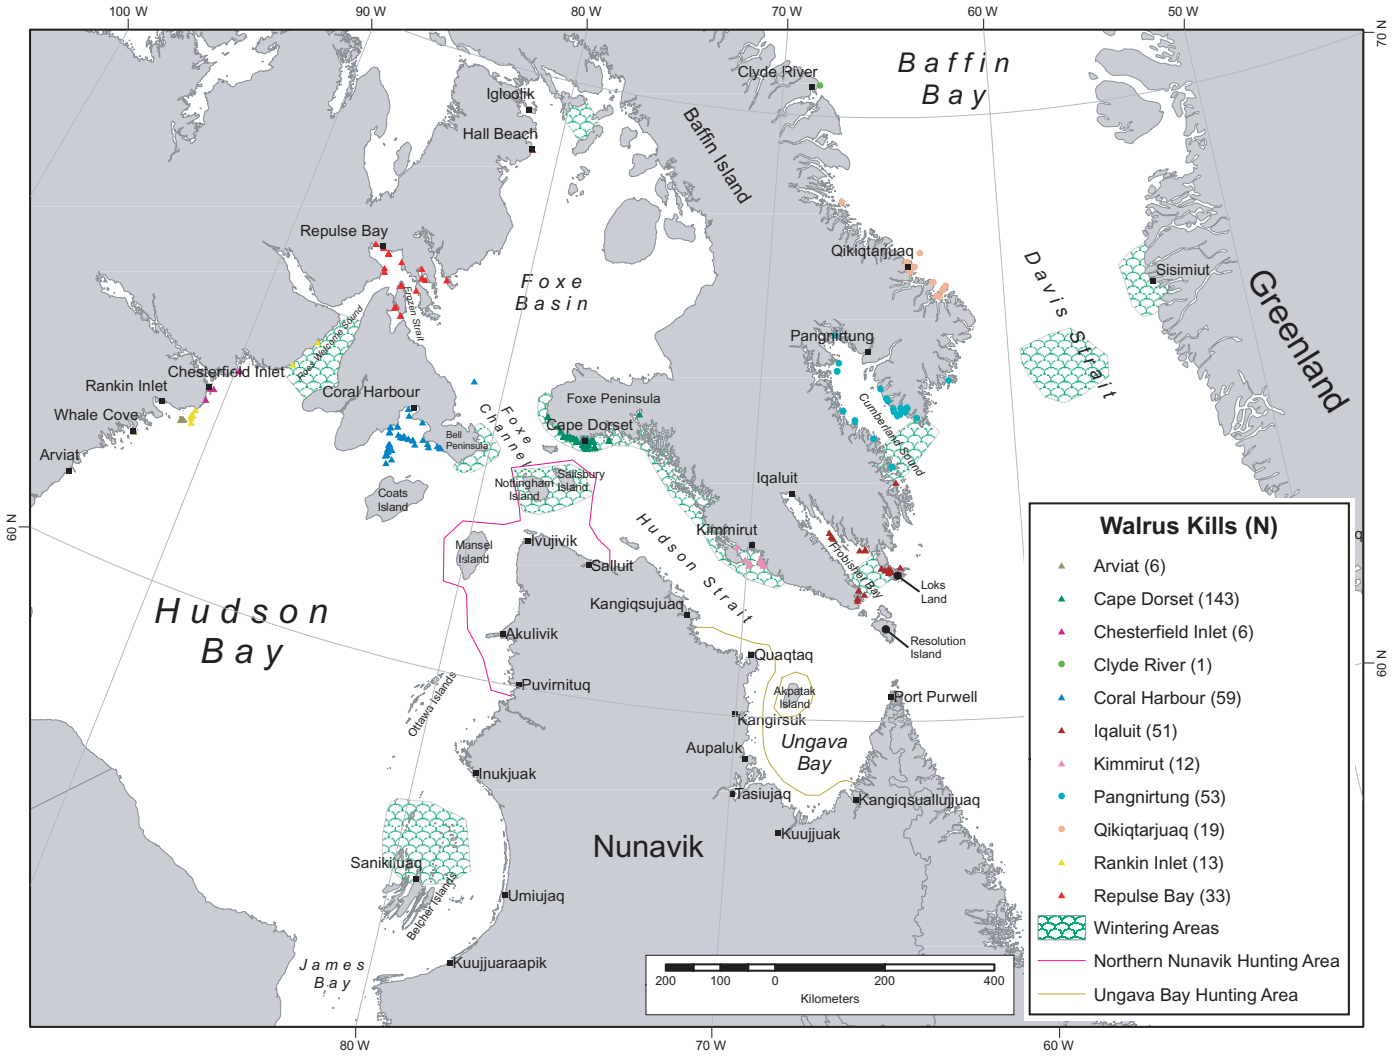

FIG. 6. Hudson Bay–Davis Strait walrus harvesting locations for Arviat, Cape Dorset, Chesterfield Inlet, Clyde River, Coral Harbour, Iqaluit, Kimmirut, Pangnirtung, Qikiqtarjuaq, Rankin Inlet, and Repulse Bay (Priest and Usher, 2004), Nunavik harvesting areas (interpreted from COSEWIC, 2006), and wintering areas (Born et al., 1995). Each kill symbol may represent more than one animal killed; N is the number of walruses reported by each community in the Priest and Usher (2004) database.

Foxe Basin stocks), both communities rely on a single interbreeding population that is characterized by primarily local movement.

Hudson Bay–Davis Strait

Walrus are found at several widely dispersed areas in winter (Fig. 6), including Roes Welcome Sound, Foxe Channel, the north shore of Hudson Strait, pack ice in Davis Strait, and probably (based on harvest dates) the mouths of Frobisher Bay and Cumberland Sound (Orr and Rebizant, 1987; Born et al., 1995; Priest and Usher, 2004; COSEWIC, 2006). There are no data to determine whether significant numbers of walrus change wintering areas between or within years.

Cape Dorset reports landing at least a few walrus almost every month, with peaks in March and November, which is the same time when Kimmirut lands about 75% of its catch (Priest and Usher, 2004). These communities may be sampling at the level of the population (wintering aggregation) that may include multiple stocks.

Walrus in HBDS are hunted at many other communities in Nunavut and Nunavik as well, usually in the open-water season. Harvests in Nunavut tend to be close to the communities, with little overlap of hunting areas. In Nunavik, however, the hunting areas of many communities overlap (Fig. 6). Along western Hudson Bay, three communities land a few walrus every year from coastal areas between Whale Cove and Roes Welcome Sound, usually in May to September. Hunters from Repulse Bay hunt mostly in Frozen Strait, with peak harvests occurring slightly later than in communities immediately to the south (Priest and Usher, 2004). It is possible that walrus at the west end of the HBDS stock are hunted by all these communities.

The distribution of HBDS walrus stretches 1500 km from east to west, along 2500 km of coastline, so clinal variation might be expected. Outridge et al. (2003) examined the lead isotopes of walrus landed at Repulse Bay,

Coral Harbour, Akulivik, Loks Land, and Sisimiut, as well as samples from FB and SEHB. They found statistical differences in $^{206}Pb/^{207}Pb$ ratios between Coral Harbour and both Akulivik and Sisimiut, which were not different from each other, as well as in $^{208}Pb/^{207}Pb$ ratios between Sisimiut and both Akulivik and Coral Harbour, which did not differ from each other. There were too few samples from intervening sites to allow statistical analysis, but there appeared to be some overlap between adjacent sites. Outridge et al. (2003) concluded that most communities were harvesting walrus that inhabited different geological areas, while noting overlap in adjacent values.

The temporal and spatial distribution of walrus harvests is consistent with Outridge et al.'s (2003) concept of local stocks that overlap each other along a cline. Peak harvests tend to occur from May to September and must reflect widespread availability. Four communities on northeast Hudson Bay report peak walrus harvests that overlap in both time (August–September, Priest and Usher, 2004) and space (Fig. 6), and share a stock. Conversely, seven communities on Ungava Bay (Fig. 6) hunt at Akpatok Island, mostly in July-August, a period concurrent with peak landings at Repulse Bay and Coral Harbour. Concurrent harvests in two locations over 800 km apart suggest different stocks.

Both Pangnirtung and Iqaluit hunters take 95% of their walrus between May and November over large areas that may overlap (Fig. 6). Some walruses are taken the rest of the year, but that does not reject the hypothesis that some walrus from southeast Baffin Island migrate to West Greenland for the winter breeding season. Those remaining in Canada may be immature animals, mature non-breeders, breeding animals that breed in both countries in different years, or animals that remain in Canada all year and that are joined seasonally by walrus from Greenland.

Walrus in the HBDS area have not been subjected to intense genetic scrutiny. Preliminary studies (NAMMCO, 2006) included the contradictory results that walrus from eastern Hudson Bay and Hudson Strait were both genetically different than walrus in West Greenland and also served as a source for West Greenland walrus. In these analyses, it was presumed that there was not an unsampled population between Hudson Strait and West Greenland (L.W. Andersen, pers. comm. 2005), but no samples from southeast Baffin Island walrus were available. A clinal model leads to two hypotheses: that southeast Baffin Island walrus will be intermediate between West Greenland and Hudson Strait walrus, and that southeast Baffin Island walrus will be the major source of immigrants to West Greenland.

Born et al. (1995) speculated there may be subunits within the HBDS range, but they noted the absence of data by which to partition this group. More recent data indicate that two groups of northern Quebec communities, one centered on Ivujivik and one in Ungava Bay (Fig. 6), share stocks with nearby communities in the group. Reviewed isotope analyses suggest that Nunavut communities harvest local animals, while the genetic studies suggest differences between animals harvested in different communities, but both types of studies were limited in geographic coverage. The range of HBDS walrus includes seven known wintering areas, and it is possible that many communities are harvesting from several stocks derived from one or a few populations (wintering aggregations). While evidence of subunits within the HBDS range has increased, it is not yet sufficient to define that substructure.

Southern and Eastern Hudson Bay

Walrus winter at the floe edges around the Sleeper and Belcher archipelagos (Fig. 7) (COSEWIC, 2006). The nearest neighbouring winter concentrations are in the HBDS population range, around Ivujivik-Nottingham-Salisbury islands and Bell Peninsula-Foxe Peninsula (Priest and Usher, 2004; COSEWIC, 2006), and they are likely separated from the SEHB population by distance and ice (Fig. 6).

Judging by information from the main hunting areas, dispersal from winter areas in the open-water season seems limited. Hunters from Sanikiluaq and Inukjuak hunt among the Sleeper and Belcher islands. Between June 1996 and May 2001, Sanikiluaq reported landing 25 walrus. Only 11 of those 25 reports included location data, but those 11 walrus were all taken at the north end of the Belcher Islands and at the Sleeper Islands (Priest and Usher, 2004). The harvest at Sanikiluaq occurs mostly in September and October (92% of 25 animals over five years, Priest and Usher, 2004). Hunters from Inukjuak hunt in the same area (Fig. 7) at about the same time. The locations of harvests reported by Kuujjuarapik and Umiujaq are unknown, but numbers may be small (Brooke, 1994, 1995).

Communities north of Inukjuak on the east side of Hudson Bay (Puvirnituq, Akulivik, Ivujivik, Salluit; Fig. 6) are thought to hunt the HBDS population. Hunters from Akulivik, the nearest community outside the SEHB area, hunt in September and October, so their hunt overlaps the Belcher-Sleeper hunt in time, but not in space as they hunt farther north, around Nottingham and Salisbury islands (Fig. 6). Walrus occupy the shoals near Cape Henrietta Maria in July-October at least, with several peak counts in September and October (COSEWIC, 2006). It is possible that some walrus that summer one year at Cape Henrietta Maria could summer in other years at the Belcher-Sleeper islands or even farther north, where they could be available to Akulivik hunters.

However, harvested walrus at Akulivik differed from those landed at Inukjuak. Muir et al. (1995) found significant differences in organochlorine concentrations and profiles in walrus landed at these two communities, which they attributed to differences in diet. Lead isotope ratios ($^{208}Pb/Pb^{207}$) and trace element profiles both showed significant differences between Inukjuak and Akulivik samples (Outridge and Stewart, 1999; Outridge et al., 2003). Concentrations of heavy metals appeared to differ between

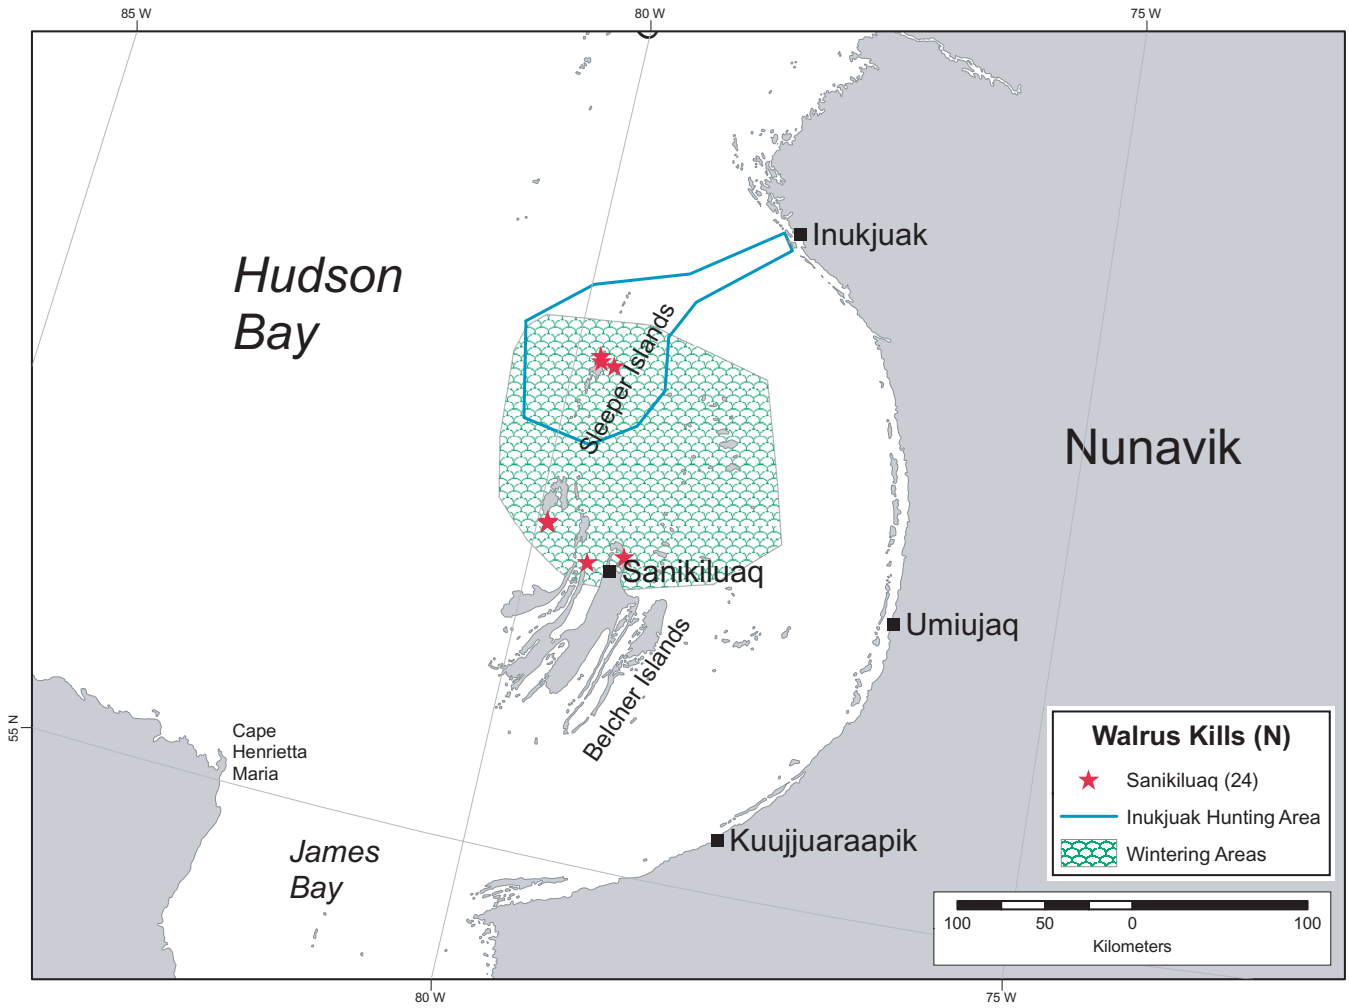

FIG. 7. Southern and Eastern Hudson Bay walrus harvesting locations for Sanikiluaq (Priest and Usher, 2004), Nunavik harvesting areas (interpreted from COSEWIC, 2006), and wintering areas (Born et al., 1995). Each kill symbol may represent more than one animal killed; N is the number of walruses reported by each community in the Priest and Usher (2004) database.

Inukjuak (Hg: 8.00 µg/g dry wt; Cd: 19.0 µg/g dry wt) and Akulivik (Hg: 4.20 µg/g dry wt; Cd: 30.0 µg/g dry wt), but sample sizes were small (9 and 4 respectively), and these differences were not statistically significant (Wagemann and Stewart, 1994).

Born et al. (1995) defined the SEHB population mostly on the basis of distribution, noting that evidence for separating it from other walrus groups in northeast Hudson Bay was not strong. Since then, new information shows significant stock differences between walrus landed at Inukjuak and at Akulivik. There are no new genetic data by which to assess the degree of interbreeding among walrus from southern and northern Hudson Bay and no new evidence to suggest subdividing this stock.

West Atlantic

Walrus were once common in the Gulf of St. Lawrence and around Nova Scotia but had been extirpated by the mid-1800s (Reeves, 1978). Five walrus were reported in the Gulf between 1992 and 1996, in four different sightings. Walrus are seen occasionally on the coast of Newfoundland (Kingsley, 1998) and Nova Scotia (Richer, 2003). Whether these observations mark recolonization of former range or random wanderings of a few individuals is unclear. Should they not be itinerant animals, the population size is small.

CONCLUSIONS

None of the new information presented here or published since the review by Born et al. (1995) refutes previous separation of stocks. It does, however, suggest further subdivision of some stocks of walrus in Canada (Table 2). Specifically, the Baffin Bay stock now appears to be three stocks: the Baffin Bay stock, the West Jones Sound stock, and the Penny Strait-Lancaster Sound stock. The Foxe Basin stock appears to be two stocks: North Foxe Basin and Central Foxe Basin. There is evidence of clinal variation in the Hudson Bay-Davis Strait stock. No changes are suggested for the SEHB stock.

TABLE 2. Summary of walrus stock revisions.

Previous Stock Designation (Born et al., 1995)	Proposed Stock Designation	Rationale	Comments
North Water (Baffin Bay-east Canadian Arctic)	West Jones Sound (WJS)	Distinguished from BB by distribution data (tags, harvest sites, survey observations, hunter observations)	Data are required to determine if this stock is a breeding population isolated from walrus wintering in east Jones Sound.
	Penny Strait–Lancaster Sound (PS–LS)	Distinguished from WJS by distribution data (tags, survey observations); Pb isotope analysis (TIMS)	Data are required to determine if this stock is also a breeding population isolated from walrus wintering in east Jones Sound and to evaluate differences between wintering areas (Dundas Polynya and east Lancaster Sound) within its range.
	Baffin Bay (BB)	Residual; Potential for further subdivisions	Pb isotope data show clinal variation between east Jones Sound and NW Greenland but sample sizes were small and new boundaries cannot be established.
Foxe Basin	Northern Foxe Basin (NFB) Southern Foxe Basin (SFB)	N and S stocks distinguished by Pb isotope ratios and distribution of harvest sites	Data are required to evaluate if these stocks form a single population.
North Hudson Bay–Hudson Strait–SE Baffin Island–N Labrador	Hudson Bay–Davis Strait (HBDS)	No change	Pb isotopes suggest clinal variation within this stock but new boundaries cannot yet be established. Data are required to assess movement of walrus between Canada and Greenland and in Canada.
Southern and Eastern Hudson Bay	Southern and Eastern Hudson Bay (SEHB)	No change	Data are required to evaluate relationships with other stocks and within the range of the SEHB stock

The new stock definitions are proposed here for three reasons. The first relates to management. It is more conservative to conclude erroneously that there are more stocks than to assume that there are fewer stocks (Taylor, 1997; Taylor and Dizon, 1999). Thus, while data that suggest subdividing stocks may be limited, it is more cautious to accept those data than to ignore them.

The second is that the recent information offers insights into the stock context of walrus populations. Walrus once had a wide and largely continuous range in Canada (Harington, 1966; Reeves, 1978) and likely were characterized by clinal variation. I suggest that females and younger animals tended to remain in more narrowly circumscribed ranges while mature males roamed among the herds and wintered in different areas over several years. Genetically different subpopulations of deer (*Odocoileus* spp.) are prevented from becoming more different by male dispersal (Harris et al., 2002). The roving male model (Suzuki et al., 1998; Stewart et al., 2003) takes this concept one step farther, in that males not only disperse from their natal area but adult males move among several breeding groups, including their natal area, over several years. Born et al. (2005) document a male walrus that returned to the same over-wintering breeding area in east Greenland in three years (1990, 2000, and 2001). Compared to the situation in Canada, these results may reflect greater fidelity to an over-wintering area or lower availability of over-wintering opportunities in east Greenland. It is possible this male over-wintered in other areas in other years.

As walrus distribution became more fragmented, female-mediated philopatry focused the population in areas of preferred habitat, including areas with less human disturbance. The roving males maintained some genetic continuity among groups, but widely separated groups became more distinct in several attributes. The roving male model was first applied to walrus by Stewart et al. (2003) to interpret different isotopic signatures at different ages in a male's life. This model is also consistent with female philopatry and moderate, male-mediated gene flow among populations (Andersen et al., 1998; Andersen and Born, 2000), and with distributional patterns seen in the High Arctic, Foxe Basin, and northern Hudson Bay to Davis Strait.

The third reason is that the newly proposed stock delineations and interpretation of the population structure of walrus in Canada generate several testable hypotheses. In Jones Sound, more data from genetics, natural markers, and tagging that cover a wider geographic distribution are required to clarify the extent of exchange of breeding animals

between west and east wintering areas, with eastern Lancaster Sound, and with NW Greenland. Isotope signatures in the growth layers of teeth may indicate that an individual has wintered in different areas over the course of its life. Similarly, sampling throughout the range of the HBDS stock is required to test between the hypotheses of clinal variation (e.g., Owen and Baker, 2001) or more dramatic subdivisions within the continuous distribution of walrus (e.g., Hoffman et al., 2006). More generally, additional genetic information would test predictions that females and juveniles at summer haulouts are closely related, but males in predominantly male groups are dissimilar, and that the harvests at Igloolik and Hall Beach differ in mtDNA, but not in genomic DNA. Genetics, natural markers, and tagging could test the hypotheses that adult males occupy several wintering areas over their lives, but females occupy only one or two, and that summer distributions reflect the philopatric movements of females from wintering areas.

ACKNOWLEDGEMENTS

This research was funded by the Nunavut Wildlife Research Trust, Nunavut Implementation Fund of the Department of Fisheries and Oceans (DFO), and from the DFO's standard operating budget. The Greenland Institute of Natural Resources provided tag 11270. The work could not have been accomplished without continuing support from the Polar Continental Shelf Project of Natural Resources Canada. The pleasant company and capable field assistance of C. Lanthier, A. Ryan, E. Born, L. Pijamini, E. Thomson, N. Lightfoot, C. Noah, E. Pijamini, M. Baktari, O. Iqaluk, and P. Nicklen are greatly appreciated. Graphics were prepared by B. Dunn, who also assisted with location analysis. The manuscript was improved by the thoughtful comments of S. Ferguson, P. Richard, A. Ryan, B. Stewart, and three anonymous reviewers. This research was conducted under Section 52 permits from DFO and Animal Use Permits from the Freshwater Institute Animal Care Committee.

Midsummer observations on the behavior of wild polar bears (*Ursus maritimus*)

IAN STIRLING
Canadian Wildlife Service, 10025 Jasper Avenue, Edmonton, Alberta, T5J 1S6

Received February 12, 1974

STIRLING, I. 1974. Midsummer observations on the behavior of wild polar bears (*Ursus maritimus*). Can. J. Zool. **52**: 1191–1198.

Wild polar bears (*Ursus maritimus*) were observed from Caswall Tower, Devon Island (74°43′ N; 91°10′ W), from 24 July to 8 August 1973. A total of 602.7 bear hours of observations was recorded. Two types of hunting were observed, stalking and still-hunting. Of 288 hunts observed, 65 (22.6%) were stalks and 233 (77.4%) were still-hunts. All cubs observed hunted, but they exhibited great variety in patience and apparent skill. Scavenging and intraspecific competition for possession of kills were observed. When threatened, adult females with cubs were not subordinate to bears of any other age or sex classes. A diurnal rhythm was recorded in which bears slept most during the latter third of the 24-h cycle and least in the first third. The average of 17 sleeps longer than 60 min was 465 ± 301.3 min.

Basking ringed seals (*Phoca hispida*) alternated between lying flat and raising their heads to look about for predators. The mean duration of the lying and looking phases was 26.3 and 7.0 s respectively (n = 591 and 580). The variation between individual seals was greater than within individuals. If a group of seals hauled out together, all individuals maintained watchful behavior; no single animal acted as a "sentry" for the others.

STIRLING, I. 1974. Midsummer observations on the behavior of wild polar bears (*Ursus maritimus*). Can. J. Zool. **52**: 1191–1198.

De la tour Caswall dans l'ile de Devon (74°43′ N; 91°10′ O), on a observé des ours polaires (*Ursus maritimus*) en nature, du 24 juillet au 8 août 1973. On a pris note des observations durant 602.7 heures-ours. Les ours pratiquent deux types de chasse: la chasse en suivant la proie et la chasse à l'affût. De 288 chasses observées, 65 (22.6%) étaient du premier type et 233 (77.4%), du second type. Tous les oursons pratiquent la chasse, mais manifestent à le faire plus ou moins de patience et d'habileté apparente. On a observé les ours manger des restes et il existe une compétition intraspécifique pour les proies mortes. Lorsqu'elles sont menacées, les femelles adultes avec des petits ne se soumettent à aucun autre ours, de quelqu' âge ou sexe que ce soit. Les ours suivent un rythme journalier: ils dorment surtout dans le dernier tiers du cycle de 24 heures, alors que c'est dans le premier tiers qu'ils dorment le moins. La moyenne calculée sur 17 périodes de sommeil supérieures à 60 min est de 465 ± 301.3 min.

Des phoques (*Phoca hispida*) installés au soleil manifestent une alternance de deux comportements: en repos, couchés à plat, ou levant la tête pour surveiller les prédateurs. La durée moyenne des phases de repos et de surveillance est de 26.3 et de 7.0 respectivement (n = 591 et 580). La variation d'un individu à l'autre est plus grande que celle qu'on observe chez un même individu. Si des phoques se rendent à terre en groupe, tous les individus opèrent la surveillance; il n'y a pas de "sentinelle" faisant la surveillance pour tout le groupe.

[Traduit par le journal]

Introduction

The Canadian Wildlife Service has been conducting research on polar bears (*Ursus maritimus*) since 1961. The initial program was oriented toward the location of denning areas (Harington 1968), while more recent research has been directed toward population ecology (reviewed in Stirling and Jonkel 1972). To date, most information on behavior has been anecdotal because the bears have usually been disturbed before being sighted, although some information has been deduced from tracks.

This paper describes the midsummer behavior of wild undisturbed polar bears at Devon Island, in the Canadian High Arctic.

Materials and Methods

Polar bears were observed on the annual ice of Radstock Bay and Gascoyne Inlet, and the intermediate peninsula of land on SW Devon Island, Northwest Territories, from 24 July to 8 August 1973 (Fig. 1). Observations were made from the top of Caswall Tower (234 m) with 10 × 50 Bushnell binoculars and a 15 to 60 × Bausch and Lomb zoom balscope. Twenty-four-hour daylight permitted continuous observation of polar bears at all times when they were visible.

Most terms are self-explanatory but two should be noted. "Still-hunting" means that a bear lies, sits, or stands still by a pool or breathing hole waiting for a seal to come to the surface. Data were pooled in the category "lying (undetermined)" when I could not determine if a distant bear was sleeping or lying down still-hunting.

Ringed seals (*Phoca hispida*), the main prey species of polar bears, often bask on the sea ice, but they punctuate

Can. J. Zool. Downloaded from www.nrcresearchpress.com by DALHOUSIE UNIVER on 06/24/13
For personal use only.

these resting periods by frequently raising their heads to look about. The frequency of head-raising was examined quantitatively for 20 seals for periods of up to 20 min duration (5 h 22 min total) to examine the protective value of this behavior in relation to polar bear predation.

Results and Discussion

A total of 602.7 bear hours (36 063 min) of observations was recorded. At one point, observation was continuous for almost 7 days (166 h). Additional qualitative notes (not included in the above totals) were made on bears not kept under continuous observation. Three individuals were observed continuously for over 70 h (one for over 90 h) before moving out of the range of vision or disappearing. Data were recorded for adults, subadults, and females with $1\frac{1}{2}$- and $2\frac{1}{2}$-year-old cubs.

Most details of the bears' activities could be determined up to a distance of about 7 km with the balscope. Although bears could be seen up to about 11 km distant, only major categories such as walking, standing, or lying could be determined with any degree of certainty.

Time Budget of Activities

Table 1 summarizes the proportion of time bears spent in each activity.

Two major categories may be noted. Even though there was some overlap, hunting (stalking and still-hunting) made up 24.4% of the total, while 66.6% of the time was spent inactively (sleeping, lying, and still-hunting). Except for the time that the bears actually spent stalking a seal on the ice, I considered walking as a separate category because sometimes when bears were travelling they went right past seals they could have stalked.

Hunting Behavior

Hunting fell into two categories, still-hunting and stalking, with several variations on each method. The three most common still-hunting stances were lying on the stomach (88.2%), standing (8.4%), and sitting (3.4%). Occasionally a crouching position was observed, but not frequently enough to be significant in the total.

The mean duration of lying still-hunts (55.1 ± 77.2 min, $n = 135$) greatly exceeded those of standing still-hunts (12.0 ± 16.0 min, $n = 52$) or sitting still-hunts (7.9 ± 13.2 min, $n = 36$). The mean durations of sitting and standing still-hunts were not significantly different from each other ($t = 1.25$, df = 88, $P > .2$), but both were significantly different from that of the lying still-hunt ($t = 3.63$, df = 171, $P < .001$ and $t = 3.96$, df = 187, $P < .001$ respectively). I interpret those results to mean that the principal method of still-hunting is lying, possibly because it is the easiest position in which a bear can remain motionless for a protracted period of time and presents the lowest silhouette against the sky (when viewed from below by a seal). The sitting and standing postures may simply provide

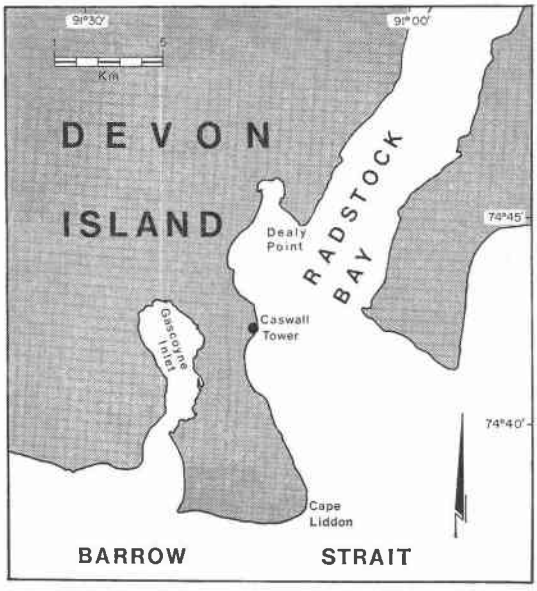

FIG. 1. The study area at SW Devon Island, N.W.T.

TABLE 1

The proportion of time polar bears spent in each activity from 24 July to 8 August 1973

Activity	No. minutes of observations	% of total
Sleeping	10 717	29.7
Walking	9 009	25.0
Still-hunting		
Lying	7 438	20.6
Sitting	285	0.8
Standing	709	2.0

relief from remaining in one position for a protracted period of time. However, a minimum of movement is made when the bears change postures because sound is readily transmitted through the ice into the water and a seal will not normally use a particular breathing hole if it hears a noise at the surface. Similar long periods of silent motionless waiting by Eskimo (Inuit) seal hunters using harpoons to still-hunt for ringed seals at breathing holes have become legendary in arctic literature (e.g. Hall 1864).

The mean length of the lying still-hunts of adult males ($x = 100.3 \pm 101.7$ min, $n = 41$) was significantly longer than for an adult female with a cub ($x = 57.5 \pm 72.6$ min, $n = 33$), probably because those of the female were often terminated prematurely by an interruption from the cub ($t = 2.77$, df = 74, $P < .01$). This conclusion is supported by the fact that although all cubs observed did lying still-hunts, the mean length was 17.1 ± 28.1 min, which was significantly shorter than those of their mothers ($t = 4.02$, df = 64, $P < .01$). The cub usually terminated its hunt before its mother and proceeded to walk about the area, eventually arriving beside the female and interrupting her. Only once did I observe an adult female, about to still-hunt, threaten her cub to make it remain at a distance.

Polar bear cubs usually remain with the adult female for $2\frac{1}{2}$ years although some may do so for longer. All of the cubs observed participated in seal hunting but there was great individual variation in both their manner and patience. The samples were too few for statistical comparison but some points may be made. The older cubs ($2\frac{1}{2}$ years) hunted more independently and at greater distances from the female than did the younger cubs ($1\frac{1}{2}$ years), i.e. up to 1–2 km apart compared with a maximum of about 0.5 km for $1\frac{1}{2}$-year olds.

Each of the two $2\frac{1}{2}$-year-old cubs caught a seal by still-hunting, although the mean duration of their hunts contrasted greatly; 2.6 min ($n = 15$) versus 28.0 min ($n = 4$). The seal caught by each bear was a young of the year (4–5 months old), suggesting that the less experienced prey may be more susceptible to young bears learning to hunt.

One of the $1\frac{1}{2}$-year-old cubs had a mean still-hunt duration of 41 min ($n = 4$). When hunting, this cub behaved like an adult. Similarly, on 2 April 1972, I followed an orphaned $1\frac{1}{3}$-year-old cub for several kilometers in the Beaufort Sea area. Its tracks showed an investigative pattern that did not appear to differ from that of an adult. Thus, it appears that even though there may be considerable variation among individuals, learning about hunting takes place at this early age. A major problem that such a small bear might encounter could be the difficulty of killing a large seal.

The most dramatic method of hunting to watch is the stalk of a basking seal. When a hunting bear saw a seal on the ice, it used one of two methods to try to get close enough to make a sudden dash and attempt to catch the seal before it went into the water. The bear either lowered its head and crept forward in a semi-crouched position, using whatever irregularities there were on the surface of the ice for cover or it slipped into the water and crept circuitously through the interconnected channels and pools that interlace the surface of the sea ice in summer. The distance between the bear and the seal at the time the final rush was made was difficult to estimate from several kilometers away but it appeared to be about 15 to 30 m. In no instance was a forepaw observed being used to cover the conspicuous black nose.

Although the stalking of seals by polar bears has often been commented on in the popular literature (e.g. Freuchen and Salomonsen 1959), probably because of its spectacular nature, that technique constituted only 22.6% (65/288) of the hunts observed in this study. No kills, or even near misses, were made by the nine bears that used the "walking stalk" a total of 38 times. In comparison, one kill and several near misses were made by the nine bears that used the aquatic stalk a total of 27 times.

The "aquatic stalk" was a specialty of one adult female in particular and she did 19 of the 27 such stalks observed. In addition she had a most individual style. While the other eight bears observed all lay flat in the water as they crept along, the whole hindquarters of this female stood vertically up in the air. It was interesting to note that the presence of this slowly moving white object did not appear to alarm the seals, even at fairly close range.

The other style of aquatic hunting observed involved the bear actually swimming under the ice between holes, surfacing to breath and look about, and diving again. The bears had such control that they could surface, breath, raise

Can. J. Zool. Downloaded from www.nrcresearchpress.com by DALHOUSIE UNIVER on 06/24/13
For personal use only.

their heads slightly to look, and submerge without making a ripple in the water. The main value of this method appeared to lie in the possibility of surprising a seal by coming up through its exit hole, although it was used to stalk specific seals on at least two occasions. On one occasion a polar bear stalked a bearded seal in a series of dives for almost 300 m and finally missed it by less than a meter.

Efficiency of Hunting

A total of five ringed seals were caught in the 602.7 bear hours of observation, an average of one kill per 120.5 bear hours, or one kill per 5 bear days. This apparently low success rate was probably partially a product of ice conditions. There is a great abundance of natural holes in the ice during summer, any one of which a seal could surface through. This must lower a bear's probability of success at any particular hole, compared with still-hunting during winter or early spring, when there is a limited number of breathing holes, all of which must be maintained by the seals themselves.

Four kills were made by still-hunting and one by stalking (success rate of 1.8% and 1.5% respectively). Considering how infrequently kills were made, it would seem far more efficient, in terms of caloric expenditure per kill, to still-hunt rather than walk many kilometers in search of seals to stalk.

Feeding Behavior

Immediately after being captured, seals were taken away from the water's edge onto the ice and were bitten several times about the back of the head and upper neck. In the instances I observed, feeding on the seal began immediately afterwards. The only exception to this pattern in the five observations was when a $2\frac{1}{2}$-year-old cub caught a seal and ran about the ice with it, stopping periodically to shake or bite it. Twenty-three minutes after the cub caught the seal its mother noticed and went to the cub, and they both began to feed immediately. C. Jonkel (personal communication) has observed two cases in which a bear carried a seal carcass up to 2–3 km inland.

A total of 10 bears were observed feeding on the five freshly killed seals. When feeding, one or both forepaws were put on the carcass while the bear bit into the body and tore up. In all cases, the bear began eating at about the middle of the body. The skin and fat were eaten first, sometimes in a very exacting manner. For example, one bear about 0.5 km distant was observed carefully using its incisors like delicate clippers to remove only the fat from the carcass, leaving the meat. That bear, a $2\frac{1}{2}$-year-old that had just been deserted by its mother, also did two other interesting things: firstly, it left an estimated 20% of the fat and all of the rest of the carcass and secondly, in classical canine fashion, tried to cover the remains by turning its back and attempting to scratch bits of snow and ice over the remains. No similar behavior has been previously reported in polar bears, although C. Jonkel (personal communication) has seen it twice.

Data on the natural duration of feeding on a fresh kill were difficult to collect because feeding at three of the five kills was interrupted by other bears. Possibly this was why the two bears referred to earlier carried carcasses inland. One adult of unknown sex fed uninterrupted for 30 min and left the remains completely, while the subadult mentioned in the above paragraph fed for 72 min, went back to still-hunting, and returned twice more to feed on the carcass for periods of 10 and 20 min during the ensuing 171 min.

When more than one bear fed on a carcass at the same time, it became severed into two or more pieces after the skin and fat were removed. In all the instances observed, large pieces of the seal were left on the ice by the bears that first fed there. All of these carcasses were scavenged by other bears and it seems likely these remains could be important to the survival of subadults, or cubs orphaned unnaturally early, before they become completely self-sufficient.

Another important feature of feeding behavior was washing. After an initial feeding period of 20 to 30 min, a bear typically went and stood with its forepaws at the edge of, or actually in, a pool of water. The bear then licked off the upper and lower parts of the paws and its face, alternating between rinsing and licking. The washing procedure was repeated every 5 to 10 min thereafter. At the termination of feeding, up to 15 min might be spent in a final washing. From its frequent occurrence in all observations, it is apparent that washing is an integral part of feeding behavior in the polar bear.

Sleeping and the Diurnal Rhythm

When sleeping, polar bears lay either on their sides with their backs to the wind, or on their stomachs with their hindquarters to the wind. Cubs lay in the lee of the female. The ice in the study area lacked pressure ridges or other substantial irregularities that might have been used for protection from wind.

The mean duration of 17 sleeps longer than 60 min was 465 ± 301.3 min (7 h 45 min). The longest single sleep recorded was 1407 min (23 h 27 min). Data from cubs were not included because their sleeping activities were largely determined by the female.

In 3 of the 17 observations, the bear slept on a gravel beach. Three kilometers south of Caswall Tower I found two sleeping pits dug by bears in the gravel ridges, similar to those described by Jonkel *et al.* (1972) on the west coast of Hudson Bay. The only other such pits recorded in the high arctic were recorded by Jonkel (personal communication) at Maxwell Bay, 17 km east of Radstock Bay and on the north coast of Devon Island.

Plotting of the total number of minutes of sleep on a 24-h basis (Fig. 2) indicated a diurnal fluctuation with significantly less sleeping in the first third of the day than the last ($\chi^2 = 989.8$, $P < .01$).

The diurnal sleeping pattern of the polar bear can be interpreted in relationship to the behavior of its major prey species, the ringed seal. Like several other species of polar pinnipeds, the maximum numbers of ringed seals haul out on the ice in the afternoon and minimum in the early hours of the morning, at which times they feed (Stefansson 1921; Smith 1973). Thus, the maximum number of seals are in the water, returning to the surface periodically to breath during the "night." Since polar bears appear to prefer still-hunting to stalking, the most advantageous time to hunt is when the probability of a seal surfacing at any particular hole is maximal, which is in the early hours of the morning. Of the five seals caught during the study, three were in the first third of the 24-h period, one in the second, and one in the latter third (Fig. 2).

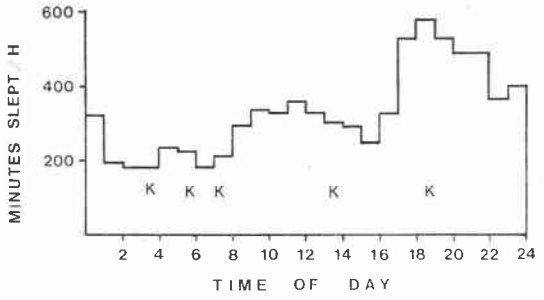

FIG. 2. Diurnal rhythm of sleeping by polar bears in midsummer. (K denotes the time a seal was killed by a polar bear.)

Swimming

Polar bears are strong swimmers and during the observation period 4.1% of the total time (24 h 26 min) was spent in the water. Bears of all ages and sex classes swam voluntarily. The data for all animals observed longer than 360 min (6 h) were pooled to determine the following proportions of time spent swimming by bears of each age and sex class: adult ♂ = 0.78%; adult ♀ = 0.62%; adult and subadult of unknown sex = 8.2%; and cubs = 4.50%. Clearly, the younger polar bears spend the most time in the water.

For the most part, the younger animals swam in pools and open leads without any apparent purpose. On several occasions cubs sprinted across the ice and dove into the water head-first in a manner similar to the final rush of an adult bear for a seal at the end of a stalk.

One bear brought what appeared to be seaweed up from the bottom, ate parts of it, and dove for more. Similar behavior has been documented in other areas (Lønø 1970; Russell 1971).

Two single smaller adults of unknown sex spent several hours at a time swimming in a particular direction along leads or between holes in the ice. One bear swam about 8 km, returning only momentarily to the ice surface to look about before reentering the water. Submergence times of 37, 40, 55, and 72 s were recorded.

Polar bears dove in two ways. The most common was to go down head-first, leaving the rear out of the water until the thrust of paddling drove the bear under. The other method, only used when stalking, was to surface only with the nose and then slip backwards under the water again.

Intraspecific Behavior

Meetings between unrelated polar bears were not common. Twelve encounters were seen during the study, or an average of one per 50.2 bear hours. Although the sense of vision appears to

be poor in polar bears, the sense of smell is acute so that most potential meetings of unrelated bears are avoided. Unrelated bears came into proximity of each other under two circumstances; when one bear travelled downwind toward a sleeping bear, and when food was competed for.

Adult females with cubs passed bears of unknown sex twice, and passed another family group and an adult male once each at distances of 150 and 300 m. No overt movements were made by either parties in any of the cases, although they watched each other closely while within sight and continued to peer backward over their shoulders for 10 to 20 min after separating.

An adult male came within 100 m of a larger second male lying still-hunting. The larger male simply walked about 30 m toward the smaller, which then turned and walked away for about 2 km before stopping. The simple visible effect of relative size was probably sufficient to determine dominance when both bears were clearly visible to each other. However, when a large adult male and a smaller bear of unknown sex suddenly met face-to-face swimming, both bears immediately veered away, presumably because there was nothing to permit each bear to quickly evaluate the status of the other. After swimming away about 50 m, the adult male turned and swam back toward the smaller bear, which then swam to the beach and fled to the top of the nearest hill about 0.5 km from the sea.

Predictably, when adult females with cubs twice came within 10 to 20 m of sleeping subadult bears of unknown sex, the latter fled instantly upon waking. Equally predictably, adult males dominated subadults of unknown sex sufficiently to exclude them from feeding on seal carcasses on two occasions.

Some of the outcomes of interactions between family groups and adult males were unexpected since males have always been assumed to be dominant to females with cubs. One instance of a male polar bear devouring a recently dead female with two cubs was reported by Jonkel (1970). However, the circumstances leading up to the event were unknown and it occurred in vegetated terrain rather than where visibility was unlimited.

In one instance during this study, a large adult male approached within 50 m of an adult female with a $2\frac{1}{2}$-year-old cub. She turned, lowered her head, and charged about 30 m twice and each time the male retreated. After the second encounter, the male turned and walked away on a round trip of 2 to 3 km before resettling to still-hunt where he had originally been.

A different adult female with a $2\frac{1}{2}$-year-old cub twice met adult males double her size while she was feeding on a fresh kill. In the first instance, the female and cub had already been feeding for 78 min. When the male arrived, they left immediately. The male fed for 49 min, and then for 2 h he followed the female and cub, which kept moving and watching behind them until the male finally stopped following.

Five days later, the same adult female as above killed a large ringed seal about 0.5 km upwind of a male twice her size that was still-hunting. Nine minutes later the male reached the kill. Rather than be displaced, the female lowered her head and charged for the male who also lowered his head to meet her. When they separated, the female was bleeding freely from a wound in her right shoulder and the male from a wound on his right side over the rib cage. The female then made a second charge of about 5 m toward the male, but he did not move. The male then returned the charge while the female stood firm. Then, after standing and looking at each other for about 30 s, the male, the female, and her cub all began to feed on the carcass together. After 21 min of feeding, the female and cub walked away to wash in a pool. Nine minutes later they attempted to return to the carcass but were chased off by the male. Meanwhile, a subadult of unknown sex arrived and walked back and forth seeking an opportunity to scavenge. After another 8 min of feeding, when the male went to wash at a pool, the cub approached the carcass. The male turned and ran toward the cub but when the female instantly charged the male he retreated. Then all three bears fed together again. One hundred minutes after the first encounter the female and cub left the carcass, washed, walked about 0.5 km west, and lay down while the cub licked the female's wound. Then, in a manner similar to the other adult male that interrupted this female at a kill, the adult male followed female and cub for about an hour before turning back to the remains of the carcass, which by this time was being scavenged by another female and her $2\frac{1}{2}$-year-old cub.

Can. J. Zool. Downloaded from www.nrcresearchpress.com by DALHOUSIE UNIVER on 06/24/13
For personal use only.

These observations suggest that adult males do not necessarily dominate females with cubs. Undoubtedly an adult male could win a fight to the death with an adult female but he would likely sustain serious wounds himself. It is also worth noting, with reference to potential cannibalism, that females and cubs can run much faster than adult males. Thus, it is unlikely that intraspecific predation occurs at more than an incidental level.

In the case where the adult female and her cub deserted a seal carcass without dispute, they had already fed on it for 78 min, thus greatly reducing the value of contesting possession of it.

Cubs were extremely nervous in meetings with any unrelated bear. They either stayed behind the female if she faced another bear or ahead of her if she moved away.

Behavior of Basking Ringed Seals

It is relevant to consider some aspects of the behavior of ringed seals when hauled out on the ice in relation to the constant threat of predation by polar bears.

The most characteristic aspect of the behavior of hauled-out ringed seals is that they continuously alternate between lying flat and raising their heads to look about for predators. If a group of seals haul out together, all individuals continue to maintain this behavioral sequence. No single animal plays the role of "sentry" for the others.

In this study, the mean duration of the looking phase was 7.0 $\pm$ 8.9 s (n = 591) and of lying was 26.3 $\pm$ 37.6 s (n = 580). On two occasions, with sample sizes of fewer than 10, Stefansson (1913) calculated means of 4.5 and 5.5 s for the looking phase and 30.1 and 35.6 s for lying. However, there is little chance that the polar bear could learn to alternate between periods of stalking and stillness on the basis of such averages because variation between individuals was significantly different and greatly exceeded that within the individual (F = 6.67, df = 19 and 571, $P < .01$ for periods of head raised; F = 16.4, df = 19 and 560, $P < .01$ for periods of lying). Even when the seals were lying, it seemed that little of the time was spent sleeping, for although it was not quantified, a substantial proportion of the time appeared to be spent rubbing, scratching, or lying with the eyes open. It seems likely that this degree of alertness on the part of basking ringed seals contributes to the apparent preference of the bears for still-hunting by breathing holes.

Several prey species apparently find a degree of protection from predation by being clumped in distribution. However, this does not appear to be true of ringed seals, which are usually dispersed in small groups over the ice surface available, except during the molting period in late spring when large numbers may be hauled up in restricted areas. Of 141 seal groups tallied, 99 were single, 23 in pairs, 11 in 3's, and 4, 3, 1, in groups of four, five, and seven respectively.

For a large part of the year, the ringed seal is dependent on a resource in limited supply, self-maintained breathing holes. Clumping of seals about single or closely knit groups of breathing holes would be disadvantageous for the seals in two ways. The primary one is that in the event of discovery of the breathing hole by a polar bear, a whole group of animals would be vulnerable to a high level of predation by the bear with no form of escape (because of dependence on air) short of swimming away in the hope of finding another hole and being permitted to use it by the seals resident there. The possibility of one seal using another's breathing hole is belied by two observations which indicate the species is rather antisocial: a high proportion of ringed seal sub-ice vocalization is agonistic in nature (Stirling 1973) and ringed seals held together in captivity are highly aggressive to each other compared with species such as harp seals (*Pagophilus groenlandicus*) or harbor seals (*Phoca vitulina*) (K. Ronald, personal communication). The second disadvantage associated with clumping about a single breathing hole occurs when a group basks together. Although there may be some advantage in having several seals watching for predators, if a bear stalks near enough to charge, not all seals may be able to get down the breathing hole in time, which was what happened in the only successful kill by stalking that I observed.

Acknowledgments

This study was supported by the Canadian Wildlife Service, Department of the Environment. I am particularly grateful to the following: The Polar Continental Shelf Project for logistic support; my wife, Stella, for assistance in the field; D. Andriashek and Roxy Smiley for

Distribution and Abundance of Canadian Polar Bear Populations: A Management Perspective

MITCHELL TAYLOR[1] AND JOHN LEE[1]

(*Received 13 January 1992; accepted in revised form 16 January 1995*)

ABSTRACT. Seasonal fidelity to relatively local areas and natural obstacles to movements allow the range of polar bears (*Ursus maritimus*) in Canada to be divided into 12 relatively distinct populations. These divisions are not the only ones possible, and may not be the best ones; however, they were consistent with observed movements of marked bears. The average area of sea ice (mainly annual ice) that constitutes polar bear habitat for populations within and shared with Canada was estimated to total approximately 3.1 million km^2 in April each year. The density estimates of polar bears ranged between 1.1 and 10.4 bears per 1000 km^2 with a weighted mean of 4.1 bears per 1000 km^2. The sum of polar bear population estimates within or partially within Canada is approximately 12 700. However, the available data were insufficient to quantify the precision and accuracy of some population estimates.

Key words: abundance, Arctic, bear, distribution, polar bear, population, *Ursus maritimus*

RÉSUMÉ. La fidélité saisonnière des ours polaires (*Ursus maritimus*) à des régions suffisamment délimitées et des obstacles naturels à leurs déplacements permettent de diviser leur territoire au Canada en 12 populations relativement distinctes. Cette division n'est pas la seule possible et elle n'est peut-être pas la meilleure; elle cadre cependant avec les déplacements d'ours marqués que l'on a observés. On estime à environ 3,1 millions de km^2, en avril de chaque année, la superficie moyenne de la glace de mer (surtout de glace annuelle) qui constitue l'habitat de l'ours polaire pour les populations vivant à l'intérieur du Canada, ou communes à d'autres pays. L'estimation de la densité des ours polaires va de 1,1 à10,4 ours par 1000 km^2, avec une moyenne pondérée de 4,1 ours par 1000 km^2. Le total des populations d'ours polaires dont le territoire est situé en tout ou en partie au Canada est estimé à environ 12 700 individus. Les données disponibles sont cependant insuffisantes pour quantifier la précision et l'exactitude de certaines estimations de population.
